Peptic ulcer—combined gastric and duodenal (Billington) (C) 753, (Johnson) (C) 850, duodenal, in Africans in Kenya, 209, factors in ætiology of (Allibone and Flint) 179, gastric, with hiatal hernia (Davidson) 729, in pulmonary emphysema (Flint and Warrack) 178, *see also* Aspirin
Pereira, M S, influenza A virus, 668
Pericarditis, tuberculous, 208
Perinatal Mortality Survey, 1185
Peritonitis—monilial, as complication of preoperative intestinal sterilisation (Andreassen, Eriksen, and Stenderup) 618, staphylococcal, in newborn (Jones) (C) 1233
Perkins, G, Fractures and Dislocations (R) 781
Perkins, H A, extracorporeal circulation, 284
Peroxidase staining in leucocytes (Quaglino and Flemans) (C) 1020
Persian Gulf, *see* Heat illness

Personal Papers—Visiting list, 40

Peru, ancient, preventive medicine in, 593
Phæochromocytoma, diagnosis of (Wright) 1155, (McMillan) (C) 1374
Pharmaceutical Journal, 536
Pharmacology—of pempidine (Harington Kincaid-Smith, and Milne) 6, Pharmacologic Principles of Medical Practice (Krantz and Carr) (R) 1266
Pharyngitis, *see* Adenovirus
Pharynx, diverticula of (LA) 404
Phear, D N sarcoidosis 1250
Phenol—infection of, to ease pain epidermal (Finer) (C) 1179 subarachnoid (Brown) 975, (Brown) (C) 1179
Phenylbutazone in treatment of temporal arteritis (Björkman) 935
Phenylketonuria, *see* 5 Hydroxytryptophan
Phenytoin sodium *see* Convulsions
Phillips, A, glycosuria (C) 586
Phosphatase, *see* Transaminase
Photocopying unit inexpensive (Kark and Lockett) (C) 748, (Redman and Weale) (C) 902
Physics for Anæsthetist (Macintosh Mushin, and Epstein) (R) 78
Physiology—Clinical Physiology of Physical Fitness and Rehabilitation (Jokl) (R) 676 of motor cells 796
Pickering, Sir G, neologisms (C) 215, (C) 375
Pink disease, unusual source of mercury in (Scopes) (C) 421
Pinkhas, J, hæmoglobin (C) 1180
Pinto, O de S, bronchitis (C) 1011
Pitt, R., Craft and Frauds of Physic Exposed, 39
Pituitary gland—antidiuretic activity in bloo after stimulation of neurohypophysis in ma (Bisset and Lee) 715 screw-implantation ^{90}Y into (Forrest, Blair, and Valentine) 19
Placenta, selective transfer of serum protei by, in rhesus (Bangham, Hobbs, and Terr 351
Plasma, *see* Blood
Plastics in intraocular surgery (LA) 196
Platelets, *see* Glandular fever
Plaza de los Reyes, M, chloroquine (C) 158
Pleura—biopsy of (A) 408, (Mestitz) (C) 52 in diagnosis of pleural effusion (Mesti Purves, and Pollard) 1349, effusion from rheumatoid arthritis, 943, hæmorrhag effusion from, as manifestation of scurv (Rozner and Lloyd) 393, (Parker) (C) 699
Pneumoconiosis, *see* Lungs
Pneumonia—endogenous lipid, 833 *see als* Influenza

Points of View—Danger! doctors at wor (Forbes) 1226—Evolution and illne (Harper) 92—Progressive non conformism i lateral geniculate nucleus of man (Menkes 1368

Poisoning by—arseniuretted hydrogen in tank cleaners (Doig) 88, carbon monoxide, acut renal failure due to muscle necrosis i (Loughridge, Leader, and Bowen) 349, glutethimide (Horler and Rowell) (C) 584 mercurised lawn sand (Scopes) (C) 421 metaldehyde (Spighel and Alroy-Spighel) (C 1017, *see also* Food poisoning
Poláček, L, disseminated sclerosis (C) 1069
Poliomyelitis—antibody response following intradermal and oral administration of formalinised poliomyelitis vaccine (Connolly, Dick, and Corkin) 333 centre, new, at Hendon Isolation Hospital London, 51, diseases resembling, 796, inoculation, death after, 368, paralytic, bone lengthening after (Ring and Ward) 551, physiology of motor cells, 796, prognosis of limb inequality following paralytic (Ring) 1306 rehabilitation after, 796, vaccination, 198, 592 796, 798, 1173, vaccine booster dose of (P) 1292, vaccine tonsillectomy and (Christie) (C) 747, (Mills) (C) 849
Politzer W M, 17 ketosteroids 778
Pollard, A C, pleural biopsy, 1349
Poller, L, coronary paradox (C) 1068
Polunin, I, N Borneo 1005
Polyneuropathy, recurrent, and cortisone (A) 627
Polyp, nasal, causing oral tumour and hæmatemesis (Taylor) (C) 1126
Pomeranze, J iron deficiency (C) 850
Poole G tuberculosis (C) 1066
Poole, J C F, colour index 550 (C) 910
Population, optimal size of (P) 1182, (Roberts) (C) 1286 (Taylor) (Jackson) (C) 1373
Porphobilinogen in urine in porphyria (Haeger) 606
Porphyria, urinary δ-aminolævulic acid and porphobilinogen in (Haeger) 606
Porteous C R, residents (C) 531
Postgraduate Medical School of London, 1074
Potassium, *see* Hypokalæmia, Pregnancy
Powell J H, 'Armadillo 779
Power, D J, suxamethonium (C) 1285
Power, S, *nephrectomy, 1257*
Practical Allergy (Harris and Shure) (R) 1048
Practice of Nuclear Medicine (Blahd, Bauer, and Cassen) (R) 1357
Pratt, D A H blood urea 1088
Pratt, R T C, anxiety states 347
Prednisolone—effect of, on absorption of vitamin B$_{12}$ in pernicious anæmia (Gordin) (C) 46 *see also* Asthma Pancreas
Preedy J R K parturition 1096
Pregnancy—anæmia in (LA) 1360 defibrination syndrome in (Sharp Howie Biggs, and Methuen) 1309 diabetes in 314 duration of (Rost) (C) 270 halothane s inhibitory action on contractility of human pregnant uterus (Embrey Garrett and Pryer) 1093 Heart

Disease and Pregnancy (Burwell and Metcalfe) (R) 246, Management of Twins in Pregnancy and Labour (film) 913 megaloblastic anæmia of (Giles and Shuttleworth) 1341, radiography of pelvis in (Williams) 1008, sodium and potassium, total exchangeable, in non pregnant women and in normal and in pre-eclamptic pregnancy (MacGillivray and Buchanan) 1090, (Robinson) (C) 1180, (MacGillivray and Buchanan) (C) 1375, toxæmia (Burton-Brown) (C) 42, (Sophian) (C) 1234 (Scott) (C) 1336, *see also* Anæmia, Liver, Parturition, Pregnanediol, Sex

Pregnanediol in plasma in human pregnancy (Deshpande and Sommerville) 1046

Prematurity, hyperbilirubinæmia in (Newns and Norton) 1138

Preregistration posts (Savidge, Wolman, and Davies) (C) 745

Prescribing cost of, 39, 105

Present Sterilizing Practice in Six Hospitals (Nuffield Provincial Hospitals Trust) (LA) 1359

Pressley, T A, hospital dust 712

Price, A U, bronchitis, 719

Primer of Cerebral Palsy (Russ and Soboloff) (R) 1159

Principles and Practice of Medicine (Davidson) (R) 1048

Principles of General Surgical Management (Dudley) (R) 26

Principles of Internal Medicine (Harrison) (R) 1266

Principles of Ophthalmoscopy (Erbaugh) (R) 26

Principles of Research in Biology and Medicine (Ingle) (R) 888

Prisons—1116, conditions in (P) 1338, report on, for 1957 (LA) 565

Prizes—Cameron prize, 219, Handcock prize, 857 John Hunter prize, 857, Nobel prizes (A) 1002, Raymond Horton-Smith prize 1294

Progesterone, *see* Parturition

Properdin—method of assay of (Bianchi and Ghirardo) (C) 49, system (A) 1218

Prostate gland—cancer of (Riches) 596, prostatectomy anæsthetic technique and other factors affecting prognosis (Ellis and Leatherdale) 1189 (Ainley-Walker) (C) 1335

Prostitution (P) 1229

Proteins—fractionation of serum-proteins by ion-exchange chromatography 834 in serum of rhesus selective placental transfer of (Bangham, Hobbs, and Terry) 351, malnutrition and pancreas (Shaper) (C) 746, (Leitner) (C) 1016, metabolism of, during corticosteroid therapy (West) 877, Nilevar used to suppress catabolism of, in acute renal failure (McCracken and Parsons) 885, proteinuria of renal tubal disorders (Butler and Flynn) 978

Pryer, D L., halothane 1093

Psychiatrists, more for Birmingham 378

Psychiatry—case-book in teaching of (Davies, Davies, and O Neill) 34, Explorations in Social Psychiatry (Leighton, Clausen, and Wilson) (R) 888 management of chronic psychoneurosis in general practice (Watts) 362, (Johnston) (C) 424 of children (A) 1108 posts for senior hospital medical officers (Knox) (C) 1011, (Kidd) (C) 1235 Psychiatry in Modern World (Strauss) (R) 354 psychopath, treatment of (A) 249 psychotherapy, future of (Nand) (C) 1289 rehabilitation in (A) 737 (correction) 806 research into, in Illinois State (Smythies) 689, social origins of (A) 134, training in (Harris) (C) 1182

Psychobiology (Meyer) (R) 194

Psychology—anxiety states following vestibular disorders (Pratt and McKenzie) 347 clinical importance of obsessional personality (Folkson) 1220 Collected Papers (Winnicott) (R) 564 Comprehensive Dictionary of Psychological and Psychoanalytical Terms (English and English) (R) 1266, decline of father-image (LA) 625 Emotional Factors in Pulmonary Tuberculosis (Kissen) (R) 1214 Humanistic Psychology (Cohen) (R) 782 Neurotic Distortion of Creative Process (Kubie) (R) 1103 of laboratory animals (Watson) (C) 747, (Hume) (C) 802 (Zangwill) (C) 851 Psychopathic Personalities (Schneider) (R) 1358, *see also* Psychoses

Psychoses—Amphetamine Psychosis (Connell) (R) 732 Study of Major Psychoses in English County (Shepherd) (R) 26, *see also* Influenza, Schizophrenia

Psychotherapy, *see* Psychiatry

Public health—History of Public Health (Rosen) (R) 246, in Israel, 579, Public Health in Tropical Countries (Ajose) (R) 1104

PUBLIC HEALTH—Anthrax and bone meal fertiliser (Green and Jamieson) 153—Antivaccinal gamma globulin in smallpox prophylaxis (Peirce, Melville, Downie, and Duckworth) 635—Bronchitis and acidity of urban precipitation (Gorham) 691—Carbon dioxide in harvested grain, 531—Chemical preservatives in food, 368—Cholera in Asia, 418—Citrus fruits, preservation of, 531—Fallout on farm, 900—Flies, campaign against, 255—Fluoridation of water 592, 741 refused in Worcestershire, 418, stopped at Andover, 204—Grain silos, danger in, 1338—Health departments, more publicity for, 743—Home care, 955—Hospital bedclothes, 743—Influenza this winter, 531—Mass-radiography campaign in Liverpool, 1277—Ministry of Health's report for 1957, 1119—Mustard gas burns? 418—National Insurance sickness benefits, 317—Occupational hazards in bone-meal industry (Lamb) 151—Poisoning by arseniuretted hydrogen in tank cleaners (D g) 88—Poliomyelitis, vaccination against, 92, 798, 1173—Prevention, 955—Radio link forward-scatter, 900—Smog in S E Lancs, 1338—Strontium-90 and malignant disease, 691—That damned word health (Go don) 638—Typhoid fever and oysters, 1072—Water-suppliers, regrouping of, 255—X irradiation too much? 1173—*See also* Infectious diseases, Vital statistics

Puerperium, megaloblastic anæmia of (Giles and Shuttleworth 1341

Puerto Rican families in New York, 647

Page 1-4 are missing

are 11 6 beds per 1000, but only some 80 admissions per 1000 per year The only fully documented and detailed studies of bed requirements in this country, those of the Nuffield Trust, suggest that we have more beds than we need for our present turnover Certainly we need nothing like the 14 beds per 1000 that were suggested in the memorandum on development of consultant services, or the 8 or so non-mental beds per 1000 suggested in some of the hospital surveys of 1943–44

Modern development is toward putting the acute psychiatric unit and the acute geriatric unit in the general hospital, and beds provided for one purpose should be so arranged that they can be equally well used for another, most of our current new planning at a rate of some 3 beds per 1000 has a reasonable margin. It is vital, however, to avoid cramping the outpatient and diagnostic departments and operating-theatres These are the real key departments, beds are secondary to them and can be far more easily and economically increased if they are really proved necessary by experience Whatever new hospital development is planned there should be space for addition

Development is, therefore, likely to be on the lines of replacement of multiple, small, bad, old hospitals by larger, well-planned, modern hospital units in smaller numbers and in many areas with fewer beds in all. We then face the problem of how far this process of concentration should be carried There are various limiting factors in this It is commonly accepted in Britain that hospitals should not be too large The service in a city of the size of Sheffield, for instance, serving 600,000–700,000 persons, should not be concentrated in one central group of buildings British thinking is against what amounts to a hospital town, a unit so large as to be cut off from the community of which it is or should be a part and drawing patients too far from their own localities So far as the big cities are concerned, opinion in England favours the main area general hospital of the order of at most 600 beds, perhaps with associated special facilities including an acute psychiatric unit and facilities for the care of the chronic sick, and sometimes a small number of detached units—for instance, a long-stay annexe or a maternity unit. Such a hospital is large enough to provide adequate specialist units in all the ordinary specialties It is easy to devise a pattern for one of our cities, say, Liverpool with a central teaching hospital of larger size and an inner and outer ring of general hospitals, each of 600 beds or so, disposed at suitable points of confluence of public transport for the convenience of the public. Obviously this sort of pattern will not be reached for many years because it involves replacement of most of the existing hospitals It must be flexible because succeeding generations will certainly want to vary it, in detail if not in essentials, but any new building now could be arranged to fit in with such a plan without throwing away effort on patching or extending unsuitable old hospitals

Outside the big cities the needs of substantial county towns are relatively clear A single general hospital, perhaps with some detached annexes for long-stay cases, can provide ultimately all the hospital service that is needed The mistake that can be made is that long-term planning can be distorted by a mistaken desire to conserve unsatisfactory pieces of old hospitals which will never fit efficiently into a new unit; or, worse still, several separate hospitals, each too small, may be preserved

Elsewhere much more difficult considerations arise. Broadly, public transport determines the foci at which hospitals should be developed People should be able to get to their hospitals as they are able to get to towns for other purposes The special problems arise where, as in West Cornwall, there is a multiplicity of small towns each with its own small hospital. In such places ultimately the small units must give way to a central general hospital which will be an adequate base for the development of specialist services The right place is largely determined by the integration of bus and rail services The most satisfactory population grouping is of the order of 100,000 upward, with an upper limit around a quarter of a million Local considerations of transport, site location, and past practice must come into these decisions, for a uniform pattern supposedly ideal would inevitably be stultifying

There are some population groups which are so detached as to make necessary hospital provision on a smaller scale than would normally be considered. Places like Berwick and Aberystwyth are very far from any main centre and serve populations too small to support the general hospital of 250 beds or so which would normally be regarded as a minimum Geography makes it necessary to have such detached units, but they should be at least large enough to provide work for locally resident physician, surgeon, and obstetrician and visiting specialists in other fields The general hospital with no locally resident specialist staff is an anachronism

We must guard against the vanity of too firm, remote planning, until there is some experience with modern area hospitals There is insufficient basic information, and however clear may be theoretical concepts developed at the centre they must often be modified in the light of local knowledge and feeling The problem is to avoid a sentimental dispersal of effort which would too greatly reduce the effectiveness of the hospitals we provide No attempt has been made to discuss the general-practitioner cottage hospital because, although we have many such, their use varies greatly and no clear pattern for their future can be discerned There are too many serious lacunæ in the provision for specialties to contemplate much new development otherwise, except in giving general practitioners access to beds especially for maternity cases

Infectious disease is a declining problem both in and out of hospital Separate hospitals for these diseases can have no place in future planning unless it be in the largest cities, and even there I doubt whether they will survive long Tuberculosis is by no means conquered yet, but the mortality has fallen by two-thirds and morbidity by more than a quarter, already many beds for tuberculosis are redundant and more become so yearly The day of the separate sanatorium is probably short, and treatment of tuberculosis within the foreseeable future will probably be undertaken largely in special wards of general hospitals In turn, there will be a reduction in the demand for thoracic surgical facilities for tuberculosis while there has arisen a new problem in cancer of the lung, which is certain to grow for some years to come. Yet this disease presents a smaller problem than tuberculosis in the demand it will make upon hospital beds, for it is either extirpated by surgery or it is much more rapidly progressive than tuberculosis Cardiac surgery has increased rapidly and will remain with us, but probably not to produce any great further increase in the load. Special units for neurosurgery and plastic surgery probably need material further increase, but they in turn will reduce the load on general and traumatic surgery. Pædiatric departments grew rapidly in the early years of the service, but that growth has passed its peak five years ago and it is doubtful whether we will continue to need so many beds as we have now, in areas such as London, Manchester, and Liverpool a pronounced decline has occurred and the total pædiatric admissions, starting at 91,205 in 1949, rose to a maximum of 121,208 in 1952 and fell to just over 100,000 in 1956 Other special departments, such as genito-urinary surgery, will probably grow, but if they do it will be at the expense of general surgical facilities which they replace in part

Early ambulation after surgery and shorter stay will reduce the number of surgical beds required for the same number of patients, but the surgical waiting-lists are so long and are falling so slowly that more facilities are needed Even with more operating-theatres and appreciably faster turnover, it may well be that the present requirement will remain and some territorial redistribution will certainly be needed On the other hand, medical beds are far less heavily pressed, although in some areas they are manifestly too few Between these two main specialties much geater flexibility is needed, freeing beds for medical cases in the first three months of the year, when respiratory illness is at its height, and returning them for surgical work in later months of the year

Probably the most striking changes will occur in the use of beds for the mentally ill In the past five years there has been a rapid increase in the provision of treatment for the mentally ill outside hospital, and the probable development of the future is in psychiatric units at general hospitals rather than in large numbers of beds in detached mental hospitals New psychiatric outpatients, other than those seen for mental deficiency, doubled in number between 1954 and 1956, probably because of an increase not so much in illness as in readiness to accept early treatment The separate mental hospital will be with us for many years yet, but it is likely that new provision will be mainly at general hospitals with inpatient, day-hospital, and outpatient facilities Experience in some of the psychiatric units of general hospitals in the Manchester region and elsewhere suggests that, in this way, a much smaller number of beds can provide for a given population than has been thought necessary in the past

Much of this comment on the hospital service is by way of forecasting trends The precedents show that most forecasters have been wide of the mark I pretend to do no more than mark some trends already discernible which seem to me most likely to survive There remains the major issue I said at the beginning that the health service was primarily one of home care If that is so, the hospitals must be organised primarily for the support of home care They are consultative centres for special diagnosis and treatment, but they must be more than that They are not the centres of general practice, but they must be accessible to the general practitioner In some hospitals there is already clearly realisation of the necessity of closer liaison between special and general medical practice As specialism becomes more complicated and more abstruse, this association becomes more than ever necessary The family doctor is the only person who sees the patient whole in relation to his family and his job, as well as to his illness It is necessary, therefore, that the family doctor should not merely have diagnostic aids from the hospital but also be enabled to make his own peculiar contribution to the assessment and care of the patient who goes to hospital, both when he is there and when he has returned home The sojourn in hospital is a brief incident in the patient's life, in a foreign environment, it may have a continuing effect It is important that that effect should be as favourable as medicine as a whole can devise, but that is only practicable if there is close partnership between those inside and those outside hospital, whatever their profession

POSTGRADUATE MEDICAL SCHOOL, LONDON, W 12

BEFORE the introduction of mecamylamine, all effe ganglion-blocking drugs used in the therapy of h tension were quaternary ammonium derivatives T drugs are not freely diffusible across cell membr including those of the gastrointestinal tract (Paton Zaimis 1952) Since their absorption from the gut is incomplete, and unpredictable, oral therapy is difficu control and often ineffective In contrast, mecamyla is a secondary amine which is freely and rapidly abso from the gut (Milne et al 1957), and is therefore al given by mouth

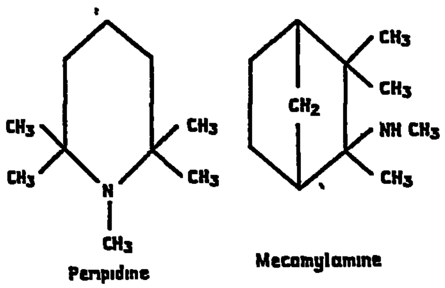
Although mecamylamine has become very popula the treatment of hypertension, it has several disadvant

Since its excretion is slow and irregular (Allanby Trounce 1957, Milne et al 1957) toxic effects from overd may be prolonged for several days, sometimes with dang life *Of these effects, paralytic ileus is the most impor* Resultant vomiting and diarrhœa cause reduction of blood-flow with further delay in excretion of the drug prolongation of toxic effects Patients with mecamylamine have been diagnosed by unsuspecting surgeons as case acute intestinal obstruction, and exposed to the dange unnecessary laparotomy (Grant and Boyd 1957, pers observation 1958) Mecamylamine diffuses freely into central nervous system, and accumulation within the brain lead to tremors and incoordination (Schneckloth et al 1 Harington and Kincaid-Smith 1958)

In view of these disadvantages, we were glad to st another drug of the amine, ganglion-blocking t preliminary laboratory findings of which were submit to us in October, 1957, by Messrs May & Baker L For this new drug (1 2 2 6 6-pentamethylpip dine) originally designated M & B 4486, the common na pempidine ('Perolysen', May & Baker) has been p posed While closely resembling mecamylamine, it important differences in detail which may make it a m useful antihypertensive agent It will be necess throughout to compare the pharmacology of these sup ficially similar drugs Supplies of pempidine were m available to us on Jan 1, 1958, together with detai pharmacological, biological, and toxicological data (S Corne and N D Edge, *personal communication*), n published in summary form (Lee et al 1958) An in pendent report on the basic pharmacology of pempid and other piperidine derivatives has also been publish recently (Spinks and Young 1958)

Chemistry

Pempidine, a tertiary amine, is a simple derivative of pipe dine of empirical formula $C_{10}H_{21}N$, and molecular weight 15 Fig 1 shows the structural formulæ of pempidine and me mylamine Both compounds are relatively strong bases of p about 11 0, and are therefore administered as salts Pempid is available for oral use as the bitartrate, but the hydrochlor



1—Structural formulæ of pempidine and mecamylamine In oth instances the amine radicle is surrounded by numerous nethyl groups

preferred for the intravenous route Since the drug is freely sorbed from the gut, the parenteral preparation is chiefly research interest and will have little place in practical therautics The hydrochloride contains about 80% of active mpidine base, and the bitartrate about 50% The drug has armacological and chemical properties quite distinct from ose of the much more toxic unsubstituted amines, piperidine d N-methylpiperidine This is of theoretical interest in lation to the mode of action of the amine ganglion-blocking oup of drugs Other piperidine derivatives have previously en shown to have ganglion-blocking activity (Norton and hillips 1953), but pempidine is the first to be suitable for use human therapeutics

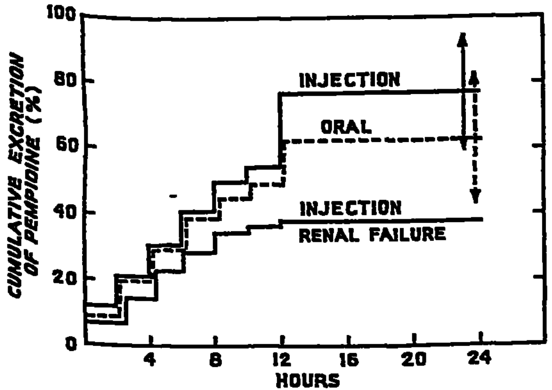
Pharmacology

The experimental design was similar to that used in an vestigation of mecamylamine (Milne et al 1957) The sults obtained in the two series of observations can thus e directly compared

bservations in Man

32 hypertensive patients without renal failure were ven pempidine, and of these 27 received continuous eatment In addition, observations were made in 2 cases f hypertension complicated by moderate uræmia (bloodrea approximately 100 mg per 100 ml)

Observations were made of the excretion of a single 5 mg ose of pempidine hydrochloride given by intravenous injection t 9 A.M Since it is known that the excretion of mecamylamine considerably influenced by variation of urinary pH (Baer et l. 1956, Milne et al 1957), the separate effects of simultaneous dministration of ammonium chloride, sodium bicarbonate, r acetazolamide on the excretion and pharmacological action f pempidine were studied in detail Ammonium chloride, g four times daily or sodium bicarbonate 3 g four times aily, was given by mouth on the day preceding and the day of injection of pempidine During trials with acetazolamide, 250 mg was given orally at the same time as the pempidine injection and a further 250 mg six hours later Urine was collected at two-hourly intervals for twelve hours after administration of pempidine, and a further twelve-hour sample from 9 P.M to 9 A.M was collected to complete a twenty-four-hour period In the cases of renal failure, additional twenty-four-hour samples were obtained on the second and third days after the injection Each first-day collection period therefore involved analysis of 8 urine samples, 7 after the injection and 1 pre-injection blank sample 32 collection periods have been analysed, comprising 8 from patients after pempidine alone, 8 from patients receiving additional ammonium chloride, 8 from patients receiving either sodium bicarbonate or acetazolamide, 2 from cases of moderate renal failure, and 6 from patients receiving a single oral dose of pempidine, ranging from 5 to 15 mg of the bitartrate



ig 2—Mean cumulative excretion of pempidine during the first 24 hours after an intravenous injection or an oral dose of the drug in hypertensive patients without renal failure, and after an intravenous injection in patients with renal failure The standard deviations of the 24-hour excretion levels are shown by the vertical lines

A total of 90 daily collections of urine from 10 hypertensive patients on continuous routine treatment with pempidine bitartrate were analysed The effects of ammonium chloride, 2 g q i d for three days, and sodium bicarbonate 3 g q i d for three days, on excretion and antihypertensive action were examined

Distribution of the drug in human blood in vivo could not be determined, because the analytical methods were too insensitive Distribution of pempidine in vitro was determined after addition of pure pempidine hydrochloride to blood sufficient to give an average concentration of 25 µg per ml Plasma-protein binding was determined after pressure filtration through 'Cellophane', and entry of the drug into erythrocytes after centrifuging Entry of pempidine into leucocytes was investigated in a sample of blood from a case of chronic lymphatic leukæmia with a white-cell count of about 300,000 per c.mm

TABLE I—STATISTICAL ANALYSIS OF EXCRETION OF PEMPIDINE IN MAN, AND COMPARISON WITH THE EXCRETION OF MECAMYLAMINE

Comparison	Mean I	Mean II	t value	P
Excretion of injected dose (I) v excretion of oral dose (II)	76%	63%	1·2	0·3>P>0·2
Excretion in acid urine (I) v excretion in alkaline urine (II)	78%	55%	2·2	<0·05
Excretion pempidine in acid urine (I) v excretion mecamylamine in acid urine (II)	78%	56%	2·9	<0·02
Excretion pempidine in normal urine (I) v excretion mecamylamine in normal urine (II)	76%	37%	6·7	<0·001
Excretion pempidine in alkaline urine (I) v excretion mecamylamine in alkaline urine (II)	55%	13%	6·0	<0·001

Observations in Rats

These experiments were designed to investigate the distribution of the drug in various body tissues 2 rats were given sublethal intraperitoneal injections of 16 mg per kg body-weight of pempidine base and a further 2 rats lethal intraperitoneal injections of 175 mg per kg Samples of blood and various tissues were analysed after one hour in the former and immediately before death in the latter Rats die in respiratory paralysis twenty to twenty-five minutes after lethal injection of the drug

Chemical Methods

Pempidine was estimated by combination with methyl-orange as first described by Brodie and Udenfriend (1945) and modified by Tillson et al (1954) A full discussion of this accurate but non-specific method has been given previously (Milne et al 1957) Tests for specificity in the particular experimental conditions were made by paper chromatography after extraction of urine samples by dichlorethane The chromatogram was developed either by butanol-acetic acid or phenol-water, and the position of the pempidine spot demonstrated by the method of Chargaff et al (1948) The only spot from urine samples which gave a methyl-orange reaction after elution had an R_f value identical with pure pempidine (R_f in butanol-acetic

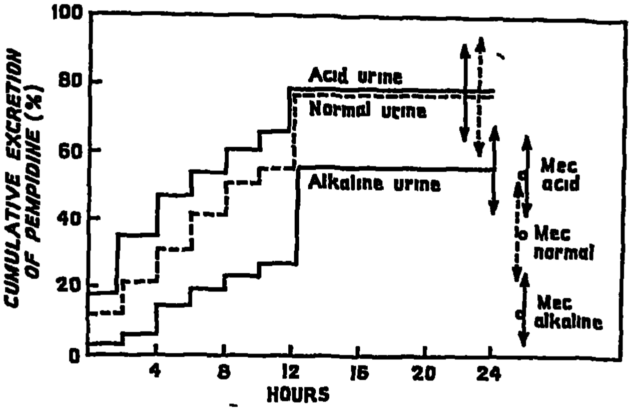


Fig 3—Mean cumulative excretion of pempidine during the first 24 hours after a single intravenous injection of 5 mg of the hydrochloride in hypertensive patients without renal failure Excretion rates are decreased in patients with alkaline urine and slightly increased in patients with highly acid urine The vertical lines give the standard deviation in each case Cumulative excretion of mecamylamine in 24 hours is shown for comparison The lowest rate of excretion of pempidine in alkaline urine is similar to the highest rate of excretion of mecamylamine in acid urine

acid 0 72) This proves that pempidine is probably excreted unchanged but does not absolutely exclude the possibility of partial metabolism to another amine of identical chromatographic properties Pure specimens of pempidine can be recovered from urine of patients treated with the drug by addition of sodium hydroxide and subsequent extraction with dichlorethane

Results

Fig 2 compares the cumulative excretion of pempidine after intravenous or oral administration in hypertensive patients, and the excretion after intravenous injection in 2 cases of renal failure An average of 76% of an injected dose and 63% of an oral dose was excreted in the first twenty-four hours This difference is not statistically significant (table I) In the uræmic patients the mean cumulative excretion was 37% of the dose in the first day, and 62% in the first two days These results suggest that pempidine is completely absorbed from the gut, and that its elimination is delayed if there is renal failure

Fig 3 compares the cumulative excretion of pempidine in patients without prior preparation, and patients receiving ammonium chloride, sodium bicarbonate, or acetazolamide The latter two agents had identical effects in reducing excretion and therefore the results have been taken together

Excretion of pempidine is considerably reduced by alkalinisation of the urine ($P<0.05$; table I) Acidification of the urine increases excretion in the first few hours after injection of pempidine, but the total cumulative excretion in twenty-four hours is not significantly changed Cumulative excretion of mecamylamine under identical conditions is included in fig 3 for purposes of comparison Pempidine excretion is about twice as rapid as that of mecamylamine in patients with urine of normal pH, four times as rapid if the urine is alkaline, and one and a half times if the urine is acid Table I shows that these differences are all statistically significant

The average recovery of pempidine from twenty-four-hour urine specimens obtained from patients on continuous therapy was 95% of the ingested dose (S D 28%) The effect of varying the pH of the urine was studied in 6 patients only Ammonium chloride had little effect in 5 patients on the excretion of pempidine or on the clinical effects of the drug In 1 patient excretion was approximately doubled on the first day of ammonium chloride, accompanied by a slight rise of blood-pressure Sodium bicarbonate had a more obvious effect Excretion of pempidine was reduced in 4 out of the 6 patients, with a parallel increase in therapeutic and side-effects due to the drug minimum twenty-four-hour recovery of pempidine in four patients during sodium bicarbonate treatment was 23 39%, 52%, and 59% respectively An example of the of alkalinisation of the urine in 1 of these patients is in fig 4

These results suggest that the drug is almost excreted in the urine Acidification and alkalinisatio the urine during maintenance treatment had less effe the case of pempidine than in that of m (Milne et al 1957)

Distribution in Blood

Plasma levels during therapy were consistently low, less than 0 5 μg per ml At these levels the analytical too insensitive to give accurate results The drug is not ficantly bound to plasma-protein, concentrations in filtrates of plasma being slightly higher than those of plasma itself In contrast, 25% of mecamylamine is boun plasma-protein Pempidine readily diffuses into eryth the mean erythrocyte/plasma ratio in human blood being *Like mecamylamine, pempidine is concentrated within* cytes, the leucocyte/plasma concentration ratio in the of leukæmic blood being 12 *0*

Distribution in Tissues

Mean concentrations of pempidine in various rat after sublethal and lethal intraperitoneal injections are give table II The drug resembles mecamylamine in tissue d tion It is concentrated in tissues rich in nuclear m especially the kidney, spleen, liver, and lung Tissue/ concentration ratios are lower in the case of pempidine tha *mecamylamine, showing that there is less tissue affinity for* former drug This partly explains the more rapid excretio pempidine, since a greater fraction of any given dose within the extracellular space and is therefore available excretion The L D $_{50}$ of pempidine is considerably higher that of mecamylamine, the L D $_{50}$ of pempidine by int

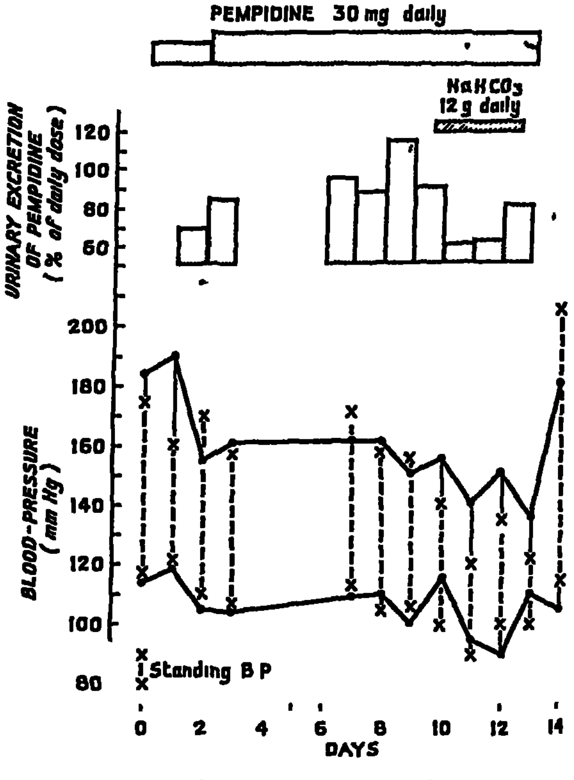

Fig 4—Effect of alkalinisation of the urine during treatment pempidine on the blood-pressure and urinary excretion of drug

* Sublethal injections (one hour after injection of drug, 16 mg free base per kg body-weight)

† Lethal injections (immediately before death after injection of mecamylamine, 60 mg base per kg body-weight, and pempidine 175 mg base per kg)

toneal injection is 175 mg per kg body-weight of active base, the corresponding L D $_{50}$ of mecamylamine is 44 mg per kg (Stone et al 1956) This higher lethal dose is confirmed by the greater concentrations of pempidine in all tissue after lethal injections of the drugs (table II) Concentrations in voluntary muscle and plasma are particularly important since muscle makes up about 33% of the body-weight and extracellular fluid about 20% Concentration of pempidine at death was 2 1 times that of mecamylamine in muscle and 3 0 times that in plasma Both drugs readily cross the blood-brain barrier and are found in relatively high concentration in the central nervous system The pharmacological effects of lethal doses of pempidine in rats are similar to those previously described for mecamylamine (Milne et al 1957) and include tremor and convulsions

Clinical Effects

Intravenous Dosage

21 patients were studied after single intravenous doses of pempidine In all except 2 cases the drug was given in a dose of 5 mg hydrochloride (4 mg base) After intravenous injection, given with the patient lying flat with the head on two pillows, the onset of action was rapid, a fall in blood-pressure being noted within two minutes in most cases The rapidity of onset of action was comparable with that after intravenous injection of pentolinium (fig 5) In some cases no fall in blood-pressure occurred in the recumbent position, but in all except 1, postural hypotension was present on standing ten to fifteen minutes after the dose In this case the patient did not respond to an intravenous dose of 5 mg, but a later oral dose of 20 mg produced a prolonged hypotensive effect

The duration of effect of a single intravenous dose, as judged by the presence of postural hypotension, was from two to six hours in patients with normal renal function The length of this period was not consistently altered in 11 patients whose urine had been made either acid or alkaline before administration of the drug

Oral Dosage

Single oral doses of 5–20 mg bitartrate (2 5–10 mg pempidine base) were given to 9 patients After an oral dose a hypotensive effect was usually observed within an hour, although in 2 cases the onset of action was delayed for three to four hours The total duration of hypotensive action was for six to seven hours after the dose, although the maximal effect lasted for only one to three hours

In 2 cases after an intravenous dose, and in 3 after a large oral dose, there was a severe fall in blood-pressure, and the effect of the drug was prolonged for as long as twenty-four to thirty-six hours One of these patients had severe oliguria which undoubtedly interfered with excretion of the drug

Continuous Oral Treatment

27 patients have been observed on continuous treatment with pempidine Initially the drug was administered thrice daily, but it was found that when the interval between doses was as long as eight hours, the blood-pressure tended to rise again two to three hours before the next dose Accordingly, it is now our practice to give the drug four times during the day, the doses being spaced at five-hourly intervals from 7 A M to 10 P M On this regime a sustained blood-pressure reduction may be obtained throughout the day If necessary the last dose at night has been doubled, thus giving a prolonged action during the night hours

In patients with impairment of renal function the drug need be given less frequently In 2 patients, with blood-urea levels of 80–100 mg per 100 ml, twice-daily dosage was sufficient to maintain a steady blood-pressure reduction

Type of Case Treated

Of the 27 patients who received continuous treatment with pempidine, 8 had malignant hypertension, with grade-IV fundi (Wagener and Keith 1939), 9 were classified in grade III, and 10 in grade II There were 10 males and 17 females, and their ages ranged from 30 to 66 5 patients had renal hypertension of varying ætiology, and 22 were diagnosed as essential hypertension

Duration of Treatment

In 24 patients treatment has been continued up to the time of writing for a period varying from two to twenty weeks (average ten weeks) Treatment was stopped after a short period in 3 patients in 1 case because of the presence of severe cerebrovascular disease, in 1, a schoolteacher, because of blurring of vision which interfered with her work, and in 1 because of persistence of head-

… 2,

in acid than alkaline urine, are concentrated in tissue containing a high proportion of cell nuclei, and easily cross the blood-brain barrier

Several differences in detail make pempidine a potentially more useful drug than mecamylamine The excretion of pempidine is more rapid, chiefly because of a lower tissue affinity for the drug Excretion of pempidine is less affected by variation in acid-base balance than that of mecamylamine The difference between an effective and a toxic concentration is probably greater in the case of pempidine

A steady hypotensive effect can be maintained throughout the day when pempidine is given orally at five-hourly intervals The dosage of pempidine can be quickly increased, owing to the rapid elimination of the drug

The chemical and physicochemical properties of pempidine and of mecamylamine in relation to their ganglion-blocking action are discussed

We gratefully acknowledge the encouragement given us by Prof J McMichael, F.R.S, and his help in the preparation of this paper Thanks are also expressed to Messrs May & Baker Ltd for supplies of pempidine ("Perolysen") and 2 : 2, 6 : 6-tetramethylpiperidine, and to Messrs Merck, Sharp & Dohme for supplies of mecamylamine and dimethylaminoisocamphane

Dosage

The dosage of pempidine required to produce an adequate hypotensive effect varied widely, a dose of 2.5 mg twice daily sufficing in one patient, whereas as much as 25 mg four times daily has been given in another case with only partial control of blood-pressure. This latter patient is also refractory to other ganglion-blocking drugs. The average total daily dose given as maintenance treatment in this series was 32.5 mg bitartrate (16 mg pempidine base).

Treatment was usually started with a dose of 2.5 mg q.i.d. It was found that the dose could be raised rapidly, increasing each dose by 2.5 mg daily until a satisfactory reduction in blood-pressure was achieved. Because of the rapid elimination of the drug from the body, it is therefore possible to reach a stable therapeutic dose level with reasonable safety in a few days—a procedure which would be fraught with danger in the case of mecamylamine.

Tolerance

In the limited period of study, no evidence has been seen of the development of "tolerance" to pempidine, analogous to that seen with hexamethonium and other quaternary ammonium compounds. In this respect the drug resembles mecamylamine.

Combination with Other Drugs

In 6 patients reserpine was added to the regime of treatment, and in 3 others a combination of chlorothiazide and reserpine was used in addition to pempidine. Preliminary observations suggest that these compounds potentiate the action of pempidine, as has been described with other hypotensive drugs.

Side-effects

The majority of patients in whom treatment with pempidine was maintained experienced some side-effects from the drug, the symptoms being similar to those usually observed during treatment with ganglion-blocking agents.

The side-effects ran parallel with the hypotensive action of the drug, coming on about half an hour after an oral dose, being at their maximum for one to two hours, and often wearing off before the next dose was due. Constipation was seen most frequently, in 18 out of 27 patients, together with dryness of the mouth (18) and blurring of vision (12). These symptoms were usually only mild or of moderate severity, in 3 patients, however, they were severe enough to be a major cause of complaint. Other symptoms were noted in a few patients, as follows: drowsiness (3), feeling of weakness (2), difficulty in micturition (2), diarrhœa (2), faintness (2), and a feeling of shakiness (1).

All side-effects disappeared rapidly on omitting the drug. This was particularly noticeable with constipation. 3 patients developed a syndrome of early paralytic ileus, with vomiting, abdominal pain, and distension, in each case these symptoms cleared completely in twelve hours after stopping pempidine. This is in marked contrast to experience with mecamylamine where a similar complication may take several days to clear—reflecting the relatively slow elimination of mecamylamine from the body.

Patients taking pempidine are instructed to try to ensure, with aperients if necessary, a bowel action before the first dose of the day. If constipation persists in spite of these measures, they are advised to omit one or two doses of the drug, a normal bowel action then occurs, and the drug is resumed in the evious dosage.

TABLE III—COMPARISON OF DOSAGE AND CLINICAL EFFECTS OF PEMPIDINE AND MECAMYLAMINE

Case	Pempidine			Mecamylamine		
	Daily dose (mg free base)	B P control	Side-effects	Daily dose (mg free base)	B P control	Side effects

B P = blood-pressure.

Comparison with Mecamylamine in Patients treated with Both Drugs

7 of the patients treated with pempidine had previously been receiving mecamylamine for at least twelve months, so that a direct comparison of the dosage and clinical effects of the two drugs was possible in these cases (table III). The dose of pempidine, expressed as the free base, which was effective in controlling blood-pressure was smaller (average 60%) than that of mecamylamine. There was little to choose between the two drugs in respect of side-effects, which were more prominent with pempidine in 2 patients, and in 2 with mecamylamine.

Discussion

Pempidine is similar in many respects to mecamylamine. Both drugs are rapidly and completely absorbed from the gut. They readily cross cell membranes and are concentrated within tissues by intracellular protein-binding, especially to nucleoproteins. The excretion of both drugs is influenced by urinary pH, clearance being decreased in alkaline and slightly increased in acid urine. This type of excretion depends on diffusion across the renal tubular cell membranes and has recently been reviewed by Milne et al. (1958).

There are, however, important differences in detail which may make pempidine a more useful antihypertensive agent than mecamylamine. While 25% of mecamylamine is bound to plasma-protein, pempidine is not so bound, and therefore all the drug in plasma is pharmacologically active. Pempidine is excreted more rapidly than mecamylamine. This is partly due to lower tissue affinity for pempidine, and partly to higher clearance-rates of pempidine as compared with mecamylamine in alkaline or weakly acid urine (Scribner et al. 1958). More rapid excretion is advantageous because toxic accumulation of the drug in the body is less likely. In addition, the dosage of pempidine can safely be increased to effective levels more rapidly than mecamylamine. Although the excretion of both drugs is influenced by change in urinary pH, variation in mecamylamine excretion is greater than that of pempidine. The hypotensive effect of pempidine is therefore less variable despite changes in acid-base balance.

The L.D.$_{50}$ of pempidine in mice is three to four times higher than that of mecamylamine (Corne and Edge, personal communication, Spinks and Young 1958). The effective dosage of pempidine in hypertension in man is usually lower than that of mecamylamine. There is probably therefore a greater margin between an effective therapeutic and a toxic dose in the case of pempidine. These preliminary results make it probable that any observed pempidine toxicity will be both less severe and briefer than that complicating mecamylamine therapy. Much longer experience will be necessary before the relative value of the two drugs in actual clinical practice can be finally established.

inflammatory cells was noted Detailed histological studies are being done but are not yet ready

GROUP 2

Four patients, aged 2, 7, 10, and 46

Case 2 —A man, aged 46, employed in a chocolate factory, was admitted on Oct 2, 1957 4 days before admission he had had "flu", he went back to work 2 days later On the day of admission he became increasingly mentally peculiar By 10 P M that day he was comatose but would grasp at objects put into his hands with a peculiar coarse tremor Next day he was deeply comatose, not responding to stimuli, and having a succession of fits His C S F contained 188 cells per c mm, (130 erythrocytes, 45 lymphocytes, and 13 polymorphs), protein was 111 mg per 100 ml, sugar 72 mg, and chloride 670 mg There were no localising physical signs His temperature was unstable, fluctuating up to 104 8°F He was treated with paraldehyde and corticotrophin, and with streptomycin as for tuberculous meningitis His temperature fell on the 3rd day after admission, and he looked much better 2 days later he was conscious again, the day after that a red rash, almost varicelliform, appeared on his back across his shoulders but not elsewhere It had disappeared 2 days later, when he was almost normal mentally though he still seemed a bit dazed On Oct 11 his C S F contained protein 42 mg per 100 ml, no globulin, 6 lymphocytes, 1 polymorphonuclear leucocyte, and 107 erythrocytes per c mm A Lange test showed 1,1,1,1,0,0,0,0,0,0 He made a complete recovery

Complement-fixation tests against influenza-A antigen gave titres of 1 64 and 1 64+ on sera taken 2 days after admission and 14 days later The C S F was inoculated into eggs and tissue cultures of HuL1 cells, no virus was isolated Complement-fixation tests for the other antigens and the Paul-Bunnell test were negative Fæces were unfortunately not available in the acute stage

At least three of these patients showed instability of the temperature-regulating mechanism One child, aged 2, recovered very slowly and was left with some residual spasticity All were treated in the acute state with corticosteroids of one kind or another, and all but one recovered rapidly

GROUP 3

Two males—one aged 2 years 8 months, the other aged 39 The onset was 11 days and 7 days respectively after an attack of clinical influenza

Case 3 —The boy was admitted to the Children's Hospital on Oct 21 with 3 days' history of malaise and constipation, 2 days' history of crying at night On admission all his reflexes were found diminished, Kernig's sign was positive, the back, but not the neck, was stiff A white cell count showed 15,400 per c mm (polymorphs 54%) His C S F contained 50 cells per c.mm (lymphocytes 90%), sugar 82 mg per 100 ml, and protein 260 mg No virus was isolated from the fæces Complement fixation for poliomyelitis was negative on two samples of serum taken 10 days apart, both gave a positive complement fixation for influenza-A soluble antigen at 1 32+ Paralysis spread upwards from below Partial respiratory paralysis was treated by positive-pressure respiration, treatment with corticoids was associated with recovery of movement from above downwards The child made a complete recovery with no residual paralysis At no time was there detectable sensory impairment

Case 4 —A radio engineer, aged 39, had "flu" early in October and returned to work 4 days after the onset 3 days later he felt tired and developed weakness of his legs and difficulty in walking and micturition 2 weeks later he noticed weakness in his arms, and he was admitted to hospital on Oct. 14 He was now febrile and had no reflexes or power of movement in his legs, his arms were weak, and he showed some nystagmus His C S F contained 200 erythrocytes and 200 leucocytes (lymphocytes 80%), protein was 445 mg per 100 ml, sugar 51 mg, and chloride 654 mg Pandy ++, Lange 0,0,0,1,2,2,2,1,0,0 His hæmoglobin was 95%, and the white-cell count 19,000 per c mm (polymorphs 87%) There was no sensation to pinprick below T 3, and no sensation to touch below T 6 Lung expansion was poor, only the diaphragm working

Next day respiration became weaker, a tracheotomy was done, and he was placed in a respirator His eye movements became limited, bilateral facial weakness appeared, and his tongue was protruded to the left Cortisone therapy was started and maintained for 4 weeks 10 days later the cranial nerves were normal and arm movement improved Over the next few days his breathing improved and he was independent of the respirator for long periods His left ankle and knee jerks returned, and his plantar responses became extensor A severe bedsore, however, persisted, and after 6 weeks in hospital he became ill and died 2 days later of bronchopneumonia

Sera taken on admission and 14 days later both gave a complement-fixation titre of 1 32 for influenza A Egg and tissue cultures inoculated with C S F and throat washings yielded no virus The cortisone treatment may well have prevented a rise in the complement-fixation titre after admission

Postmortem Findings —Patchy bronchopneumonic consolidation was found in both lungs The brain was fixed whole Histologically, perivascular demyelination was found, it was greatest in the cord, areas of demyelination being so extensive as to become confluent In the medulla the lesions were not so extensive, but one confluent area of demyelination almost surrounded one olivary nucleus Lesions were numerous in the cerebellar peduncles, especially in the middle peduncle, and were also found in the white matter near the lateral wall of the ventricle near the hippocampus major Fat-filled macrophages were seen in and around the perivascular spaces All the lesions appeared to be at about the same stage

This clinical history and the histological findings resemble closely Greenfield's (1930) second case

GROUP 4

This group comprises cases presenting with a history of an influenza-like illness followed, after an interval of a few days, by neurological illness, and where complement-fixation tests or hæmagglutination-inhibition tests, or both, for influenza remained persistently negative, and cases where the diagnosis of influenza was in doubt, or where some possible cause other than influenza was discovered There were six such patients, aged 3, 5, 6, 32, 50, and 50

Case 5 —A boy, aged 5, had headache, abdominal pain, lassitude and drowsiness a week before admission His mother noticed that he had some muscular stiffness On admission on Nov 11, 1957, his temperature was 99 4°F and his pulse-rate 120 He was apathetic, with generalised muscular rigidity His plantar reflexes became extensor but reverted to normal 5 days later His C S F contained 9 leucocytes per c mm and a slight increase in protein The muscular rigidity gradually subsided, and the boy went home

No virus was isolated from C S F or fæces, but the complement-fixation titre for influenza rose from 1 64 on serum taken soon after admission to 1 128 on convalescent sera However, poliovirus type 1 was isolated from the fæces of his cousin, aged 6, who was admitted the following day, also with 3 days' history of drowsiness, abdominal pain, and headache No paralysis developed, and he was discharged on Dec 2, in good condition Complement-fixation titres against influenza A were the same as for his cousin Influenza virus was not grown from throat swabs in either case The complement-fixation test against poliovirus heated antigen remained negative

Acute hæmorrhagic leucoencephalitis was found in only one patient post mortem Serum was unfortunately not

(Clarke et al (1958) and Henle et al (1958) have reservations about this) Accordingly we looked through some of the German and English medical journals for 1890 (the *Deutsche medizinische Wochenschrift*, *Virchows Archiv*, the *British Medical Journal*, and *The Lancet*) to see whether there was any mention of acute encephalitis associated with, or as a sequel to, clinical influenza, but we found no such case recorded, though Crome (1954) had earlier noted three reports of it in the German literature of 1892 In more recent years, however, some authors have described an association between clinical influenza and either encephalitis or the Guillain-Barré syndrome In most cases laboratory confirmation of influenza-virus infection, either by isolation or by serological methods, was lacking

Greenfield (1930) described two cases of encephalitis Holmes (1947) described six cases of atypical pneumonia, of which two were associated with polyneuritis, three with lymphocytic meningitis, and one with encephalitis Hollander (1947) reported twenty-three cases of sensory polyneuritis, of which seventeen had an influenza-like illness 1–3 weeks before onset, and two had congestion of the fauces Leigh (1946) described nine cases of encephalitis, myelitis, or polyneuritis occurring during an epidemic of influenza B More recently, cases with serological evidence of influenza A have been reported by Jennings (1952), who reported two cases of severe polyneuritis and a case of lymphocytic meningitis following attacks of influenza A Ferraro and Roizin (1957) have published a useful general review of postinfective encephalitis, and Crome (1954) gives a good review of the older literature on encephalitis associated with influenza

We have collected a number of cases where influenza-virus infection has been associated with neurological disturbance of various kinds Most occurred during the autumn epidemic, but a few occurred early this year These fell into four groups

Group 1—Fatal cases with a history of convulsions or fits or clinical "encephalitis" at the height of an attack of influenza, associated with a very congested brain at necropsy The diagnosis was confirmed by isolation of Asian-type virus from the lungs, and in one case from the brain as well When the illness had lasted 6 or 7 days, complement fixation to a titre of 1 8–1 16 could usually be got with influenza-A soluble antigen and postmortem serum Attempts to isolate virus from the lungs failed in one case but the naked-eye and histological appearance of the lungs was typical of influenza, and the necropsy was carried out more than twenty-four hours after death

Group 2—A history of encephalitis with onset from 3 days to 2 weeks after an attack of influenza In its most dramatic form this presented as confusion proceeding to coma, with flaccid limbs and little or no response to stimuli Diagnosis was made by demonstration of a high complement-fixing titre (a rise from 1 64 to 1 128 being found in one case) or by the presence, after recovery, of antibodies inhibiting hæmagglutination by Asian influenza virus, or both

Group 3—Cases presenting with ascending sensory and motor disturbance of the Guillain-Barré type

Group 4—Misleading cases

Laboratory Investigations

Sera were put up at a dilution of 1 4 against heated poliomyelitis-virus antigens (types 1, 2, and 3) and at a dilution of 1 8 against mumps soluble and viral antigens, influenza A, B, and C soluble antigens, psittacosis-group antigen, Q-fever antigen, and adenovirus antigen

For the hæmagglutination-inhibition test sera were treated with trypsin according to the method of Sampaio and Isaacs (1953) to destroy non-specific inhibitor Sera inhibiting 50% hæmagglutination of 1% human group-O cells by four agglutinating doses to an initial dilution of 1 16 or greater were regarded as affording evidence of past infection

Brain suspensions, 20% in saline solution, were made of a pool of pieces taken from cortex, white matter, basal ganglia, cerebellum, and medulla Brain and fæcal suspensions were inoculated into cultures of human-embryo liver-cells, the HuLi line established by Westwood et al (1957) was used, its sensitivity to polioviruses and adenoviruses is very similar to that of HeLa cells It is not susceptible to ECHO virus type 9 Brain and fæces from our most recent case was inoculated also into their MK 1 line of rhesus kidney-cells, which are readily susceptible to ECHO viruses

Influenza virus was isolated from 10–20% lung and/or trachea suspensions in saline-broth in 12–13-day-old eggs by the amniotic route in the usual way Where the morbid anatomical appearances strongly suggested influenza, egg cultures were usually positive where necropsy was done within 24 hours of death, and usually negative after that time, but on one occasion influenza virus was isolated about 44 hours after death

Histological preparations were made of some pieces of brain, but most of the material is still undergoing the lengthy neuropathological embedding

Illustrative Case-reports

One case-history typical of each group will be given in detail, significant aberrations from this pattern will be mentioned where necessary

GROUP 1

Six patients, aged 3½, 4, 11, 12, 30, and 44, two children were siblings

Case 1—A boy, aged 11 Developed influenza in September, 1957 He vomited copiously 4 days later and he became delirious the following day On admission to Little Bromwich Hospital 6 days after the onset he was stuporous, with cerebral irritability and a mild left facial paresis tendon-reflexes were brisker than normal, and both plantar responses were extensor A clinical diagnosis of influenzal encephalitis was made His cerebrospinal fluid (C S F) contained less than 1 cell per c mm , protein was 10 mg per 100 ml , and chloride 770 mg He rapidly became comatose and died the day after admission

Postmortem Findings—At necropsy 44 hours after death (the body having been refrigerated) the trachea showed acute inflammation, with a little thin pus within the lumen The lungs showed patchy consolidation, with only a few areas of hæmorrhage The brain appeared soft, swollen, and friable, with intense congestion of the surface vessels On section, the vessels of the white matter were found to be dilated, but there were no macroscopic hæmorrhages Influenza virus of the Asian type was isolated from a tracheal swab, though not from brain or lung Tissue cultures inoculated with suspensions of fæces and brain remained healthy

The two youngest patients presented with convulsions as the only cerebral complication From the one aged 3½, influenza virus was isolated both from the brain suspension and from a pool of lung and trachea, but the brain suspension yielded no virus when diluted 1 10, whereas virus grew in 4/4 eggs inoculated with a dilution of 1 1000 (the highest dilution tested) of the lung and trachea suspension It is not unreasonable to suspect that the pieces of brain may have been contaminated with virus in the postmortem room, because no precautions were taken to prevent this, or there may well have been virus present in the blood-stream Histological examination of a few blocks revealed no gross changes in the brains from any of these cases, no perivascular infiltration with isolated from cases in group 1 at the end of the epidemic and convalescent sera from their relatives were compared by the hæmagglutination-inhibition technique with convalescent sera and viruses isolated from uncomplicated cases of influenza in the Midlands at the beginning of the epidemic The viruses in each case had had one amniotic and two allantoic passages Eight strains of virus and eight sera were put up against each other in a " chess-board " type of experiment No differences outside the limits of experimental error were found between any of the viruses

The ætiological association of influenza, at a time when the infection was so widespread, with encephalitis or myelitis in groups 2 and 3 seems less certain Although a case could be made out for it, we feel that the evidence for a direct connection is insufficient This observation is supported by the cases in group 4 Furthermore, it is not rare to elicit a history of respiratory infection or of pyrexia preceding by a few days the onset of encephalitis occurring at times when epidemic influenza is not prevalent.

We endorse the remark of Dunbar et al (1958) that more evidence is needed

Summary

Cases are described of encephalopathy, encephalitis, or ascending paralysis associated with Asian-type influenza-virus infection The diagnosis of influenza was supported by isolation of the virus or by serological means

Cases clinically simulating postinfluenzal encephalitis, where serological tests for influenza remained negative in convalescence, or where another possible cause of encephalitis was found, are also described

An attempt is made to assess the significance of positive serological findings for influenza in cases of encephalitis at a time of epidemic spread

It is concluded that, though the hypothesis is attractive, the ætiological relationship between influenza-virus infection and " postinfluenzal encephalitis " is not proven

We wish to thank Prof W Melville Arnott, Dr R D Blachford, Dr R Fothergill, Dr J M Garvie, Dr M Jefferson, Dr A C Kendall, Dr F L Ker, Dr J C Macaulay, Dr Clifford Parsons, Dr W Carey Smallwood, Dr S R F Whittaker, and Mr J A Williams for permission to mention their patients and for details of case-records, to Dr W H J Baker, Dr W T Smith, and Dr A L Woolf for details of postmortem and histological findings, and to Mr N E Chard and Mr J R Foster for most of the serological work and virus isolations We are indebted to Messrs Lederle, Inc , for the diagnostic antigen for Q fever, and to Dr J C N Westwood and Dr F Sheffield, for the cultures of MK 1 and HuLı cells Prof C H Stuart-Harris kindly read our draft and drew our attention to Dr Crome's paper

NEUROLOGICAL DISORDERS ASSOCIATED WITH ASIAN INFLUENZA

BRIAN MCCONKEY
B M Oxon, M R C P
SENIOR REGISTRAR IN MEDICINE

R ALEX DAWS
F R C S
SENIOR REGISTRAR IN NEUROSURGERY

THE ROYAL INFIRMARY, CARDIFF

REPORTS of disorders of the nervous system during epidemics of influenza have appeared from time to time (Leigh 1946, Holmes 1947, Jennings 1952) Following the recent epidemic of influenza A (Asian), Dubowitz (1958) reported 2 cases, and further examples were given by Compton Smith (1958) and McGill and Goodbody (1958) In few cases, however, have laboratory studies adequately established that influenza was the primary disorder

During October and November we saw 4 patients in whom neurological disorders followed a febrile illness suggestive of influenza We here report these cases and give details of influenza-A (Asian) antibody titres

Case-reports

Case 1—A boy, aged 16, was admitted to the Cardiff Royal Infirmary on Nov 20, 1957 Nine days previously he had felt unwell, with headache, muscle pains, fever, and cough He was seen by his family doctor, who diagnosed Asian influenza His symptoms persisted for three days On the fourth day his fever subsided and he felt better On the evening of the fifth day his headache returned and he started to vomit Headache and vomiting increased in frequency and severity until the eighth day, when he became drowsy and was admitted to a local hospital He was transferred to the Cardiff Royal Infirmary next day

He was drowsy, irritable, uncooperative, and unable to understand or carry out simple instructions There were no involuntary movements The temperature was 98 6°F, pulse-rate 90 per minute, respiration-rate 18 a minute There was slight neck rigidity No abnormality was detected in the cranial nerves In the extremities there was slight reduction in muscle power in the left arm and leg but the tone was normal on both sides Voluntary movements of both upper limbs were poorly carried out Sensation to pin-prick and cotton-wool was normal Tendon reflexes were present and symmetrical, but the plantar responses were extensor There were no abnormal signs in other systems

Investigations—Lumbar puncture on the day of admission yielded a clear cerebrospinal fluid under a pressure of 70 mm H_2O cells, less than 5 lymphocytes per c mm , protein 20 mg per 100 ml , chloride 138 mEq per litre, sugar 80 mg per 100 ml

The blood-count was normal A radiograph of the chest revealed no abnormality An electroencephalogram on the day after admission showed a grossly abnormal record, with high-voltage slow delta waves and a little theta activity in all leads (fig 1)

Complement-fixing antibodies for influenza A produced a titre of 1/1024 (Nov 20) and 1/256 (Dec 2 and 5) By hæmagglutination inhibition the titre on Nov 20 was 1/512 for the Asian variety and less than 1/4 for the Scandinavian, Eire, and Dutch strains

Progress—His condition remained unchanged for about thirty-six hours and then steadily improved By Nov 25 he was fully alert, cheerful, talkative, and free from symptoms He had complete amnesia for events between Nov 12 and 23 The electroencephalogram taken on Nov 25 was normal

Case 2—The 13-year-old sister of the boy in case 1 was admitted to the Cardiff Royal Infirmary on the same day She taken before death or at necropsy, and no virus was isolated from lungs, central nervous system or fæces, but a respiratory infection was suggested by the following case

Case 6—A woman, aged 33, complained of cough, general malaise, and tiredness a week before admission The day before admission she vomited and could not sleep at night On the day of admission (Nov 5, 1957) she complained of weakness of her right arm and leg and subsequently became incontinent and stuporous Her temperature was 101°F, and she was having frequent convulsions All her tendon-jerks were exaggerated, her plantar responses was extensor, and she had bilateral ankle clonus Lumbar puncture yielded hazy C S F containing 1000 polymorphs and 30 lymphocytes per c mm, protein 228 mg per 100 ml, sugar 51 mg, and chloride 760 mg Convulsions persisted next day, and she died that afternoon At necropsy her brain was swollen and congested. On section very many small petechial hæmorrhages were found involving the white matter of the cerebral hemispheres almost exclusively, though the brain-stem on the right side showed similar lesions Histologically "ring hæmorrhages", with much perivascular infiltration with many polymorphs and some lymphocytes, were found Acute tracheitis was present and the trachea contained pus, but the lungs histologically showed no gross abnormality—certainly nothing to support a diagnosis of epidemic influenza Influenza virus was not isolated from brain or lung, and no cytopathogenic virus was isolated in tissue culture from brain, lung, or fæces

It is possible, but by no means certain, that this was a case of influenza-virus infection, if so, the lungs returned to histological normality remarkably rapidly It seems more likely that the tracheitis was due to something other than Asian influenza

The next case presented a similar history but the patient recovered completely

Case 7—A man, aged 50, complained of shivering and pains in the back This was on Jan 1, 1958, at a time when some Asian-type virus was being isolated in the Midlands, and a diagnosis of influenza was made Next afternoon he was found comatose, but consciousness returned gradually over the next 4 days His C S F contained 20 lymphocytes per c mm, protein was 80 mg per 100 ml, chloride 720 mg, and sugar 71 mg The complement-fixation test for influenza remained negative in convalescence, the only positive finding being a titre of 1 32 with both acute and convalescent sera against herpes simplex virus, with a mouse-brain antigen prepared according to Balducci et al (1956)

Three other patients presented with encephalitis-like symptoms following attacks of "influenza", oculomotor disturbances were common to all three, and all gave negative complement-fixation tests, and, in the two cases where they were done, negative hæmagglutination-inhibition tests also

Case 8—A man, aged 50, became confused, diplopic, and unsteady after "quite typical flu" in mid-September, 1957 His diplopia lasted only about 24 hours, but 6 weeks later, when he was seen as an outpatient, he was still unsteady, felt weak, and had trouble with his memory He was slightly dysarthric and had mild lateral nystagmus and intention tremor His gait was severely ataxic He slowly improved after this and when last seen was much better though not ready to return to work Complement-fixation and hæmagglutination-inhibition tests were negative

Discussion

The problem is whether encephalitis associated with influenza is caused in some way, directly or indirectly, by the influenza virus, or whether the relationship is a chance one During an epidemic such as last autumn's usually cases are seldom referred to a laboratory unless they have features of special interest or the diagnosis is in doubt Among the cases reported here are some where the association of clinical "influenza" with encephalitis was misleading, and less notice may well have been taken of influenza following encephalitic symptoms than of encephalitis following influenza All the cases reported here have been "selected" in this respect by the clinician or pathologist, and a statistical analysis of them would obviously not be valid

Serological evidence has been adduced by ourselves and also by others (Dubowitz 1958, Dunbar et al 1958, and others) to support the diagnosis of influenza-A virus infection in association with encephalitis Now most of these cases occurred during the epidemic spread of a virus in an almost uniformly susceptible "virgin" population It would be interesting to know what proportion of the population as a whole would have given a positive complement fixation when the epidemic had just subsided—the time when convalescent sera were taken from most of the cases under discussion Most of the sera submitted to the Regional Virus Laboratory at this time gave a positive result, but most of them were from patients with a history of "flu", and so were not representative

Other evidence was sought Dunbar et al (1958) estimated that clinical influenza affected 20% of the population, but among those admitted to hospital for any reason the infection-rate (clinical and subclinical) was probably much higher than that

In a residential school for children with damaged hearts only four of about fifty children escaped illness The fact that the temperatures of all the children in the school are taken twice daily as a routine made detection of minor illness easier Though some children had slight pyrexia for only 24 hours, their complement-fixation tests nevertheless became positive

Sera were taken in December from all the forty-two children operated on for appendicitis in the Children's Hospital, Birmingham, in September, October, and November Hæmagglutination-inhibiting antibodies to Asian influenza were found in forty Of fifty-two sera taken at random from children attending as outpatients at that hospital thirty-five had similar evidence of past infection, so had thirteen of twenty adults attending as outpatients at Little Bromwich Hospital Presumably most of these patients acquired their infection during the epidemic It therefore seems that a convalescent serum from anybody admitted to hospital, from whatever cause, during the epidemic would have had a good chance of giving a positive complement-fixation test for influenza Of a much larger series collected in Sheffield after the epidemic Clarke et al (1958) found that 44% of the population had neutralising antibodies after the epidemic, though 56% of those aged 0–10 years and 70% of those aged 10–20 gave evidence of infection In view of the very good chance of catching influenza in hospital during an epidemic, our figures agree reasonably well with those of Clarke et al (1958)

The association of influenza with the cerebral symptoms and postmortem findings in group 1 is quite clear Whether it is necessary to invoke a specific toxic or infectious action of the virus seems doubtful We could not say confidently that all the changes seen could not have been produced by the severe anoxæmia and venous congestion associated with a hæmorrhagic pneumonia persisting for several days "Encephalopathy" seems a more appropriate term than "encephalitis"

To see whether there was anything unusual about viruses from "encephalopathic" cases, strains of virus isolated from cases in group 1 at the end of the epidemic and convalescent sera from their relatives were compared by the hæmagglutination-inhibition technique with convalescent sera and viruses isolated from uncomplicated cases of influenza in the Midlands at the beginning of the epidemic. The viruses in each case had had one amniotic and two allantoic passages Eight strains of virus and eight sera were put up against each other in a "chess-board" type of experiment. No differences outside the limits of experimental error were found between any of the viruses

The ætiological association of influenza, at a time when the infection was so widespread, with encephalitis or myelitis in groups 2 and 3 seems less certain Although a case could be made out for it, we feel that the evidence for a direct connection is insufficient This observation is supported by the cases in group 4 Furthermore, it is not rare to elicit a history of respiratory infection or of pyrexia preceding by a few days the onset of encephalitis occurring at times when epidemic influenza is not prevalent.

We endorse the remark of Dunbar et al. (1958) that more evidence is needed

Summary

Cases are described of encephalopathy, encephalitis, or ascending paralysis associated with Asian-type influenza-virus infection The diagnosis of influenza was supported by isolation of the virus or by serological means

Cases clinically simulating postinfluenzal encephalitis, where serological tests for influenza remained negative in convalescence, or where another possible cause of encephalitis was found, are also described

An attempt is made to assess the significance of positive serological findings for influenza in cases of encephalitis at a time of epidemic spread

It is concluded that, though the hypothesis is attractive, the ætiological relationship between influenza-virus infection and "postinfluenzal encephalitis" is not proven.

We wish to thank Prof W Melville Arnott, Dr R. D Blachford, Dr R Fothergill, Dr J M Garvie, Dr M Jefferson, Dr A. C Kendall, Dr F L Ker, Dr J C Macaulay, Dr Clifford Parsons, Dr W Carey Smallwood, Dr S R F Whittaker, and Mr J A Williams for permission to mention their patients and for details of case-records, to Dr W H J Baker, Dr W T Smith, and Dr A L Woolf for details of postmortem and histological findings, and to Mr N E Chard and Mr J R. Foster for most of the serological work and virus isolations We are indebted to Messrs Lederle, Inc., for the diagnostic antigen for Q fever, and to Dr J C N Westwood and Dr F Sheffield, for the cultures of MK 1 and HuLi cells Prof C H Stuart-Harris kindly read our draft and drew our attention to Dr. Crome s paper

NEUROLOGICAL DISORDERS ASSOCIATED WITH ASIAN INFLUENZA

BRIAN McCONKEY
B.M Oxon, M.R.C.P
SENIOR REGISTRAR IN MEDICINE

R. ALEX DAWS
F.R.C S
SENIOR REGISTRAR IN NEUROSURGERY

THE ROYAL INFIRMARY, CARDIFF

REPORTS of disorders of the nervous system during epidemics of influenza have appeared from time to time (Leigh 1946, Holmes 1947, Jennings 1952) Following the recent epidemic of influenza A (Asian), Dubowitz (1958) reported 2 cases, and further examples were given by Compton Smith (1958) and McGill and Goodbody (1958) In few cases, however, have laboratory studies adequately established that influenza was the primary disorder

During October and November we saw 4 patients in whom neurological disorders followed a febrile illness suggestive of influenza We here report these cases and give details of influenza-A (Asian) antibody titres

Case-reports

Case 1—A boy, aged 16, was admitted to the Cardiff Royal Infirmary on Nov 20, 1957 Nine days previously he had felt unwell, with headache, muscle pains, fever, and cough He was seen by his family doctor, who diagnosed Asian influenza. His symptoms persisted for three days On the fourth day his fever subsided and he felt better On the evening of the fifth day his headache returned and he started to vomit Headache and vomiting increased in frequency and severity until the eighth day, when he became drowsy and was admitted to a local hospital He was transferred to the Cardiff Royal Infirmary next day

He was drowsy, irritable, uncooperative, and unable to understand or carry out simple instructions There were no involuntary movements The temperature was 98 6°F, pulse-rate 90 per minute, respiration-rate 18 a minute There was slight neck rigidity No abnormality was detected in the cranial nerves In the extremities there was slight reduction in muscle power in the left arm and leg but the tone was normal on both sides Voluntary movements of both upper limbs were poorly carried out. Sensation to pin-prick and cotton-wool was normal Tendon reflexes were present and symmetrical, but the plantar responses were extensor There were no abnormal signs in other systems

Investigations—Lumbar puncture on the day of admission yielded a clear cerebrospinal fluid under a pressure of 70 mm H_2O cells, less than 5 lymphocytes per c.mm., protein 20 mg per 100 ml , chloride 138 mEq per litre, sugar 80 mg per 100 ml

The blood-count was normal A radiograph of the chest revealed no abnormality An electroencephalogram on the day after admission showed a grossly abnormal record, with high-voltage slow delta waves and a little theta activity in all leads (fig 1)

Complement-fixing antibodies for influenza A produced a titre of 1/1024 (Nov 20) and 1/256 (Dec 2 and 5) By hæmagglutination inhibition the titre on Nov 20 was 1/512 for the Asian variety and less than 1/4 for the Scandinavian, Eire, and Dutch strains

Progress—His condition remained unchanged for about thirty-six hours and then steadily improved By Nov 25 he was fully alert, cheerful, talkative, and free from symptoms He had complete amnesia for events between Nov 12 and 23 The electroencephalogram taken on Nov 25 was normal

Case 2.—The 13-year-old sister of the boy in case 1 was admitted to the Cardiff Royal Infirmary on the same day She

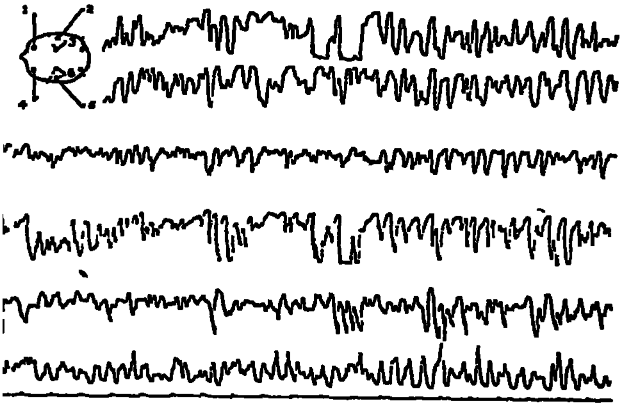

Fig 1—Case 1 electroencephalogram, Nov 21

ad been taken ill at the same time as her brother and her llness followed the same course She became drowsy on ov 18 and next morning was semicomatose She was admitted o a local hospital in coma and was transferred to the Cardiff oyal Infirmary next day

She was in deep coma There were no involuntary movenents Temperature 101 6°F, pulse-rate 100, respiration-rate 5 a minute The pupils were dilated and fixed to light The undi were normal The limbs were flaccid with symmetrically iminished tendon reflexes Both plantar responses were xtensor There was no response to painful stimuli No bnormal signs were detected in the cardiovascular or respiraory systems

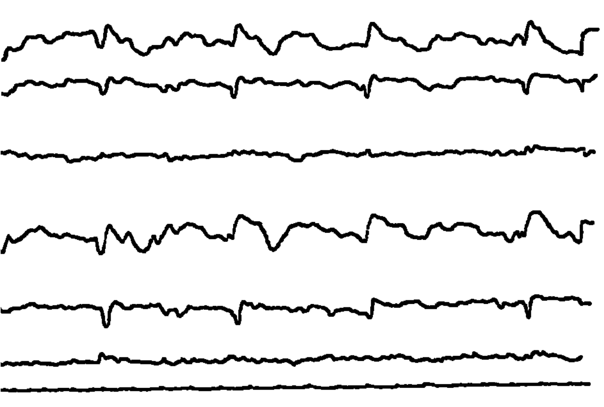
Investigations —Lumbar puncture on the day of admission roduced a clear colourless fluid under a pressure of 90 mm I_2O cells < 5 per c mm , protein 39 mg per 100 ml , chloride 24 mEq per litre, sugar 99 mg per 100 ml

Hb 15 5 g per 100 ml , leucocyte-count 11,800 per c mm 91% polymorphs) Platelet-count on Nov 25, 65,000 per mm , Dec 5, normal A radiograph of the chest revealed no bnormality

An electroencephalogram (Nov 21) showed a grossly bnormal record The tracing was very flat, but occasional low subdelta waves occurred exhibiting bilateral frontal preominance During part of the record the slow activity showed definite periodicity (fig 2) A further electroencephalogram n Nov 27 was normal

The titre of complement-fixing antibodies for influenza A as 1/2408 (Nov 20), 1/128 (Dec 2) and 1/64 (Dec 5) By emagglutination inhibition the titre was 1/480 for the Asian ariety and less than 1/4 for the Scandinavian, Eire, and Dutch trains on Nov 20

Progress —Shortly after admission her temperature rose to 04 6°F, the respiration-rate increased to 44 a minute, and her condition became critical She was treated with parenteral cortisone (50 mg six-hourly) and penicillin (1 million units six-hourly) Within four hours some clinical improvement was apparent Next day her pupils reacted sluggishly to light but there was otherwise no change in her condition Her attitude was one of decerebrate rigidity, with the upper limbs medially rotated at the shoulder joints, extended at the elbows and hyperpronated, the legs were held in extension with the feet plantar-flexed On Nov 23 she began to respond to painful stimuli, and to exhibit alternating phases of rigidity and flaccidity She remained pyrexial but the respiration-rate was less rapid On Nov 25, after six days in coma, she recovered consciousness rapidly and was able to recognise her parents She was then noted to have a foot-drop on the left, with complete paralysis of the extensors and peronei, and an area of sensory impairment to pin-prick over the dorsum of the foot This was thought to be due to compression of the lateral popliteal nerve Otherwise her recovery was uneventful When seen recently, however, she complained that writing was difficult and her script had changed in character



ig 2—Case 2: electroencephalogram, Nov 21 Electrode positions as in fig 1

The Family —The mother, father, and 2 children other than cases 1 and 2 all had febrile illnesses diagnosed as Asian influenza Complement-fixation tests were done on three who were not admitted The results were

	Date	*Complement-fixation (influenza A)*	*Hæmagglutination inhibitions*			
			(Asian)	(Scan-	(Eire)	(Dutch)
Father	Nov 25	1/32	1/64	<1/16	<1/8	<1/8
	Dec 5	1/16	1/64	<1/16	<1/8	<1/8
Mother	Nov 25	1/128	1/64	<1/8	<1/16	<1/8
Daughter	Nov 27	1/128	1/128	<1/32	<1/16	<1/4

This daughter had an episode of drowsiness and headache four or five days after the febrile illness, but recovered without treatment

These results, and those of cases 1 and 2, indicate recent infection with influenza A (Asian)

Case 3 —A woman, aged 32, was admitted to the Cardiff Royal Infirmary on Nov 26, 1957 On Oct 26 she had a short illness of three days, with aching limbs, coryza, and slight cough This was thought to be influenza On Nov 1 blurring of vision, diplopia, and occasional vomiting developed Three days later she was admitted to a local hospital, where she was found to have a loss of vertical conjugate gaze and blurring of the disc edges, and the right knee and ankle jerks were more brisk than those on the left At lumbar puncture, the fluid was clear and colourless and under a pressure of 160 mm H_2O It contained no cells, and the protein content was 30 mg per 100 ml

She was transferred to the Cardiff Royal Infirmary on Nov 26, 1957, for further investigation, but by now felt perfectly well She was alert The pupils were dilated, the right more than the left, and the reaction to light was very sluggish on both sides The pupil response to convergence was impaired, and there was limitation of conjugate upward gaze The rest of the cranial nerves were normal There were no abnormal neurological signs in the upper or lower limbs, and no other abnormal physical signs were demonstrated

Investigations —Cerebrospinal fluid (C S F) under normal pressure cells 5 per c mm , protein 37 mg per 100 ml , chloride 127 mEq per litre Blood and C S F Wasserman and Kahn tests negative Blood-count normal An electroencephalogram on Nov 27 was within normal limits

Complement-fixing antibodies for influenza A were present at a titre of 1/64 (Nov 27) and 1/64 (Dec 5) By hæmagglutination inhibition the titre was 1/128 for the Asian variety and less than 1/16 for the Scandinavian, Eire, and Dutch strains, indicating a recent infection with influenza A (Asian)

Progress —While she was in hospital the diplopia cleared up completely A lumbar air encephalogram failed to reveal any abnormality She was discharged home on Dec 9, 1957

Case 4 —A girl, aged 6 years, was taken ill on Oct 23, 1957, with headache and fever Next day she felt better but was thought to have a cold. On Oct 26 she was listless and reluctant to play She was, however, well enough to travel to Cardiff next day During the journey she began to vomit and this persisted, with pain in the back of the neck, until she was admitted to a local hospital on Oct. 30 Here she was found to be drowsy but easily rousable, cooperative, and normally oriented Temperature 100 2°F, pulse-rate 110, respiration-rate 26 a minute There was a slight increase in tone and reflexes in all four limbs The plantar responses were equivocal Signs of meningeal irritation were present Lumbar puncture produced a fluid containing 80 lymphocytes per c.mm and an increased amount of globulin

Next day she was more drowsy, the tone and reflexes in the right arm and leg were exaggerated, and the right plantar response was extensor She was transferred to the Cardiff Royal Infirmary on Nov 1 She was very drowsy, but could be roused by painful stimuli Speech was limited to the word "yes", and she did not seem to understand simple instructions Neck rigidity was present, but Kernig's sign was negative Temperature, pulse-rate, and respiration-rate were normal No abnormality was demonstrated in the cranial nerves The limbs were hypotonic. There was slight weakness of the right arm and leg, the tendon reflexes on the right were slightly more brisk than those on the left The right plantar response was extensor The abdominal reflexes were not altered. No other abnormal neurological signs were detected, and the other systems were normal

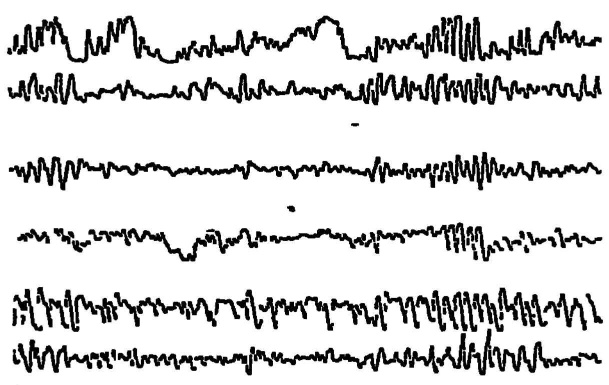


Fig 3—Case 4 electroencephalogram, Oct. 24 Electrode positions as in fig 1

Investigations —Shortly after admission the lumbar puncture was repeated pressure 55 mm H_2O, 68 lymphocytes per c.mm , protein 54 mg per 100 ml

Blood-count normal Radiographs of skull and chest normal

The electroencephalogram on the day after admission showed intermittent runs of high-voltage smooth delta waves at about 3 cycles a second in all leads A wide range of moderately high-voltage theta waves also occurred There was no subdelta or focal activity (fig 3) Complement-fixation tests gave the following titres

Date	*Complement fixation*			
	Influenza A	*Influenza C*	*Mumps*	
			S	*V*
Nov 1	1/64	1/64	1/8	1/64
Nov 4	1/64	1/64	1/8	1/64
Nov 18	1/32	1/64	1/8	1/64
Nov 27	1/64	1/32	1/8	1/32

By hæmagglutination inhibition the titre was 1/32 for the Asian variety on 3 occasions and 1/16 on Nov 18 It was less than 1/8 for the Scandinavian, Eire, and Dutch strains These figures are consistent with fairly recent infection by influenza A (Asian) virus It is likely that the febrile illness was Asian influenza, but influenza C and mumps cannot be excluded

Lumbar punctures were performed daily for four days and then at increasing intervals The cell-count rose to 1300 per c.mm on the third day after admission and then dropped steadily to 5 per c.mm on the eighteenth day At the height of the pleocytosis there was a preponderance of polymorphs, but thereafter the proportion of lymphocytes steadily increased from 60% to 90% of the total cell-count On Nov 28 the cell-count was normal The protein content varied between 40 and 80 mg per 100 ml and the sugar between 50 and 75 mg per 100 ml , and the chloride remained at about 130 mEq per litre

Progress —A provisional diagnosis of meningitis was made and she was treated with penicillin The diagnosis, however, was revised to one of encephalitis in view of the cerebrospinal-fluid findings By Nov 5 she was greatly improved and mentally alert and cooperative Speech was normal except for a nasal quality, which her parents said was normal No abnormal neurological signs could be found except for slight neck rigidity She was discharged from hospital on Nov 28 The electroencephalogram on that day showed a very great improvement

Discussion

In all these patients neurological involvement followed four or five days after the onset of a febrile illness That this febrile illness was Asian influenza appears to have been established by the results of the complement-fixation tests in 3 cases The high infectivity of the disease is shown by its spread in the family of the first 2 cases, for the other 4 members of this family had febrile illnesses, and blood from 3 showed evidence of recent infection with influenza A (Asian) Blood was not obtained from the 4th member The daughter whose blood was examined also had involvement of the nervous system following her attack of influenza She complained of severe headache and became drowsy, but recovery was uneventful Case 4 had an illness very like lymphocytic choriomeningitis, and was the only one in whom a cell response developed in the cerebrospinal fluid The illness followed what was thought to be Asian influenza, and although the results of the complement-fixation tests do not altogether exclude influenza C and mumps, we believe that the neurological disorder in this case, as in the others, followed Asian influenza.

3 of the patients (cases 1, 2, and 4) were very ill and caused some anxiety, but when recovery began it was rapid and apparently complete In cases 1 and 2 the electroencephalogram, although grossly abnormal at the height of the illness, soon reverted to normal It has since been reported that the handwriting of case 2 has deteriorated, and this is probably evidence that recovery has not been as complete as was at first thought

Summary

In 4 patients severe disorders of the nervous system followed a short febrile illness 3 of the patients had encephalitis and 1 had an illness resembling lymphocytic choriomeningitis In all of them complement-fixation tests showed evidence of a recent infection with influenza A (Asian), but in one the antibody titres for influenza C and mumps were also raised

We wish to thank Dr Idris G Jones and Mr Charles Langmaid, under whom the patients were admitted, and Dr J D Spillane for helpful criticism We are also indebted to Dr A D Evans, of the Public Health Laboratory Service, who carried out and advised us about the complement-fixation tests, and to Mr R. Marshall for the photographs

had been taken ill at the same time as her brother and her illness followed the same course She became drowsy on Nov 18 and next morning was semicomatose She was admitted to a local hospital in coma and was transferred to the Cardiff Royal Infirmary next day

She was in deep coma There were no involuntary movements Temperature 101 6°F, pulse-rate 100, respiration-rate 35 a minute The pupils were dilated and fixed to light The fundi were normal The limbs were flaccid with symmetrically diminished tendon reflexes Both plantar responses were extensor There was no response to painful stimuli No abnormal signs were detected in the cardiovascular or respiratory systems

Investigations—Lumbar puncture on the day of admission produced a clear colourless fluid under a pressure of 90 mm H_2O cells < 5 per c mm , protein 39 mg per 100 ml , chloride 124 mEq per litre, sugar 99 mg per 100 ml

Hb 15 5 g per 100 ml , leucocyte-count 11,800 per c mm (91% polymorphs) Platelet-count on Nov 25, 65,000 per c mm , Dec 5, normal A radiograph of the chest revealed no abnormality

An electroencephalogram (Nov 21) showed a grossly abnormal record The tracing was very flat, but occasional slow subdelta waves occurred exhibiting bilateral frontal predominance During part of the record the slow activity showed a definite periodicity (fig 2) A further electroencephalogram on Nov 27 was normal

The titre of complement-fixing antibodies for influenza A was 1/2408 (Nov 20), 1/128 (Dec 2) and 1/64 (Dec 5) By hæmagglutination inhibition the titre was 1/480 for the Asian variety and less than 1/4 for the Scandinavian, Eire, and Dutch strains on Nov 20

Progress—Shortly after admission her temperature rose to 104·6°F, the respiration-rate increased to 44 a minute, and her condition became critical She was treated with parenteral cortisone (50 mg six-hourly) and penicillin (1 million units six-hourly) Within four hours some clinical improvement was apparent Next day her pupils reacted sluggishly to light but there was otherwise no change in her condition Her attitude was one of decerebrate rigidity, with the upper limbs medially rotated at the shoulder joints, extended at the elbows and hyperpronated, the legs were held in extension with the feet plantar-flexed On Nov 23 she began to respond to painful stimuli, and to exhibit alternating phases of rigidity and flaccidity She remained pyrexial but the respiration-rate was less rapid On Nov 25, after six days in coma, she recovered consciousness rapidly and was able to recognise her parents She was then noted to have a foot-drop on the left, with complete paralysis of the extensors and peronei, and an area of sensory impairment to pin-prick over the dorsum of the foot This was thought to be due to compression of the lateral popliteal nerve Otherwise her recovery was uneventful When seen recently, however, she complained that writing was difficult and her script had changed in character

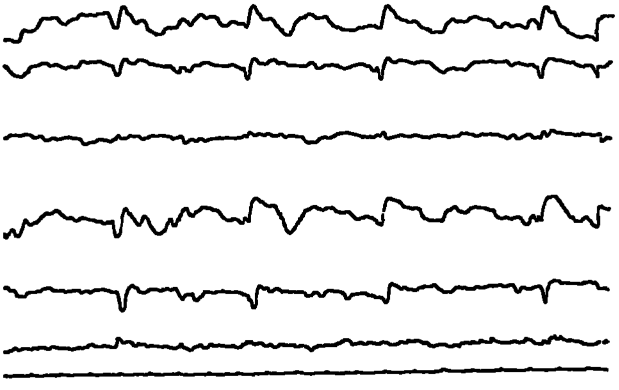

Fig 2—Case 2 electroencephalogram, Nov 21 Electrode positions as in fig 1

The Family—The mother, father, and 2 children other than cases 1 and 2 all had febrile illnesses diagnosed as Asian influenza Complement-fixation tests were done on three who were not admitted The results were

	Date	*Complement-fixation (influenza A)*	*Hæmagglutination inhibitions* (Asian)	(Scan-	(Eire)	(Dutch)
Father	Nov 25	1/32	1/64	<1/16	<1/8	<1/8
	Dec 5	1/16	1/64	<1/16	<1/8	<1/8
Mother	Nov 25	1/128	1/64	<1/8	<1/16	<1/8
Daughter	Nov 27	1/128	1/128	<1/32	<1/16	<1/4

This daughter had an episode of drowsiness and headache four or five days after the febrile illness, but recovered without treatment

These results, and those of cases 1 and 2, indicate recent infection with influenza A (Asian)

Case 3—A woman, aged 32, was admitted to the Cardiff Royal Infirmary on Nov 26, 1957 On Oct 26 she had a short illness of three days, with aching limbs, coryza, and slight cough This was thought to be influenza On Nov 1 blurring of vision, diplopia, and occasional vomiting developed Three days later she was admitted to a local hospital, where she was found to have a loss of vertical conjugate gaze and blurring of the disc edges, and the right knee and ankle jerks were more brisk than those on the left At lumbar puncture, the fluid was clear and colourless and under a pressure of 160 mm H O It contained no cells, and the protein content was 30 mg per 100 ml

She was transferred to the Cardiff Royal Infirmary on Nov 26, 1957, for further investigation, but by now felt perfectly well She was alert The pupils were dilated, the right more than the left, and the reaction to light was very sluggish on both sides The pupil response to convergence was impaired, and there was limitation of conjugate upward gaze The rest of the cranial nerves were normal There were no abnormal neurological signs in the upper or lower limbs, and no other abnormal physical signs were demonstrated

Investigations—Cerebrospinal fluid (C S F) under normal pressure cells 5 per c mm , protein 37 mg per 100 ml , chloride 127 mEq per litre Blood and C S F Wasserman and Kahn tests negative Blood-count normal An electroencephalogram on Nov 27 was within normal limits

Complement-fixing antibodies for influenza A were present at a titre of 1/64 (Nov 27) and 1/64 (Dec 5) By hæmagglutination inhibition the titre was 1/128 for the Asian variety and less than 1/16 for the Scandinavian, Eire, and Dutch strains, indicating a recent infection with influenza A (Asian)

Progress—While she was in hospital the diplopia cleared up completely A lumbar air encephalogram failed to reveal any abnormality She was discharged home on Dec 9, 1957

Case 4—A girl, aged 6 years, was taken ill on Oct 23, 1957, with headache and fever Next day she felt better but was thought to have a cold On Oct 26 she was listless and reluctant to play She was, however, well enough to travel to Cardiff next day During the journey she began to vomit and this persisted, with pain in the back of the neck, until she was admitted to a local hospital on Oct. 30 Here she was found to be drowsy but easily rousable, cooperative, and normally oriented Temperature 100·2°F, pulse-rate 110, respiration-rate 26 a minute There was a slight increase in tone and reflexes in all four limbs The plantar responses were equivocal. Signs of meningeal irritation were present Lumbar puncture produced a fluid containing 80 lymphocytes per c.mm. and an increased amount of globulin.

Next day she was more drowsy, the tone and reflexes in the right arm and leg were exaggerated, and the right plantar response was extensor She was transferred to the Cardiff Royal Infirmary on Nov 1 She was very drowsy, but could be roused by painful stimuli Speech was limited to the word "yes", and she did not seem to understand simple instructions Neck rigidity was present, but Kernig's sign was negative Temperature, pulse-rate, and respiration-rate were normal. No abnormality was demonstrated in the cranial nerves The limbs were hypotonic. There was slight weakness of the right arm and leg, the tendon reflexes on the right were slightly more brisk than those on the left The right plantar response was extensor The abdominal reflexes were not altered. No other abnormal neurological signs were detected, and the other systems were normal

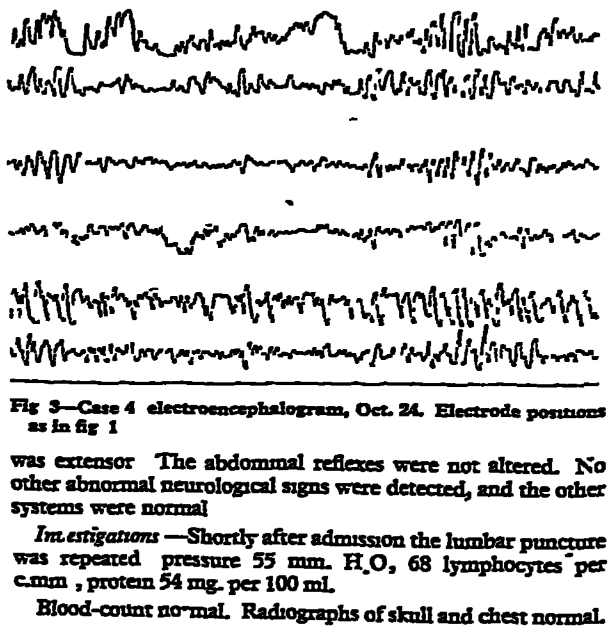

Fig 3—Case 4 electroencephalogram, Oct. 24. Electrode positions as in fig 1

Investigations—Shortly after admission the lumbar puncture was repeated pressure 55 mm. H_2O, 68 lymphocytes per c.mm , protein 54 mg. per 100 ml.

Blood-count normal. Radiographs of skull and chest normal.

The electroencephalogram on the day after admission showed intermittent runs of high-voltage smooth delta waves at about 3 cycles a second in all leads A wide range of moderately high-voltage theta waves also occurred. There was no subdelta or focal activity (fig 3) Complement-fixation tests gave the following titres

Date	*Complement fixation* *Influenza A*	*Influenza C*	*Mumps* *S*	*V*
Nov 1	1/64	1/64	1/8	1/64
Nov 4	1/64	1/64	1/8	1/64
Nov 18	1/32	1/64	1/8	1/64
Nov 27	1/64	1/32	1/8	1/32

By hæmagglutination inhibition the titre was 1/32 for the Asian variety on 3 occasions and 1/16 on Nov 18. It was less than 1/8 for the Scandinavian, Eire, and Dutch strains These figures are consistent with fairly recent infection by influenza A (Asian) virus It is likely that the febrile illness was Asian influenza, but influenza C and mumps cannot be excluded.

Lumbar punctures were performed daily for four days and then at increasing intervals The cell-count rose to 1300 per c.mm on the third day after admission and then dropped steadily to 5 per c.mm. on the eighteenth day At the height of the pleocytosis there was a preponderance of polymorphs, but thereafter the proportion of lymphocytes steadily increased from 60% to 90% of the total cell-count. On Nov 28 the cell-count was normal The protein content varied between 40 and 80 mg per 100 ml. and the sugar between 50 and 75 mg per 100 ml , and the chloride remained at about 130 mEq per litre

Progress—A provisional diagnosis of meningitis was made and she was treated with penicillin. The diagnosis, however, was revised to one of encephalitis in view of the cerebrospinal-fluid findings By Nov 5 she was greatly improved and mentally alert and cooperative Speech was normal except for a nasal quality, which her parents said was normal. No abnormal neurological signs could be found except for slight neck rigidity She was discharged from hospital on Nov. 28 The electroencephalogram on that day showed a very great improvement.

Discussion

In all these patients neurological involvement followed four or five days after the onset of a febrile illness That this febrile illness was Asian influenza appears to have been established by the results of the complement-fixation tests in 3 cases The high infectivity of the disease is shown by its spread in the family of the first 2 cases, for the other 4 members of this family had febrile illnesses, and blood from 3 showed evidence of recent infection with influenza A (Asian) Blood was not obtained from the 4th member The daughter whose blood was examined also had involvement of the nervous system following her attack of influenza. She complained of severe headache and became drowsy, but recovery was uneventful. Case 4 had an illness very like lymphocytic choriomeningitis, and was the only one in whom a cell response developed in the cerebrospinal fluid. The illness followed what was thought to be Asian influenza, and although the results of the complement-fixation tests do not altogether exclude influenza C and mumps, we believe that the neurological disorder in this case, as in the others, followed Asian influenza.

3 of the patients (cases 1, 2, and 4) were very ill and caused some anxiety, but when recovery began it was rapid and apparently complete In cases 1 and 2 the electroencephalogram, although grossly abnormal at the height of the illness, soon reverted to normal It has since been reported that the handwriting of case 2 has deteriorated, and this is probably evidence that recovery has not been as complete as was at first thought.

Summary

In 4 patients severe disorders of the nervous system followed a short febrile illness 3 of the patients had encephalitis and 1 had an illness resembling lymphocytic choriomeningitis In all of them complement-fixation tests showed evidence of a recent infection with influenza A (Asian), but in one the antibody titres for influenza C and mumps were also raised.

We wish to thank Dr Idris G Jones and Mr Charles Langmaid, under whom the patients were admitted, and Dr J D Spillane for helpful criticism We are also indebted to Dr A D Evans, of the Public Health Laboratory Service, who carried out and advised us about the complement-fixation tests, and to Mr R. Marshall for the photographs

Investigations —Lumbar puncture on the day of admission produced a clear colourless fluid under a pressure of 90 mm H_2O cells < 5 per c mm , protein 39 mg per 100 ml , chloride 124 mEq per litre, sugar 99 mg per 100 ml

Hb 15 5 g per 100 ml , leucocyte-count 11,800 per c mm (91% polymorphs) Platelet-count on Nov 25, 65,000 per c mm , Dec 5, normal A radiograph of the chest revealed no abnormality

An electroencephalogram (Nov 21) showed a grossly abnormal record The tracing was very flat, but occasional slow subdelta waves occurred exhibiting bilateral frontal predominance During part of the record the slow activity showed a definite periodicity (fig 2) A further electroencephalogram on Nov 27 was normal

The titre of complement-fixing antibodies for influenza A was 1/2408 (Nov 20), 1/128 (Dec 2) and 1/64 (Dec 5) By hæmagglutination inhibition the titre was 1/480 for the Asian variety and less than 1/4 for the Scandinavian, Eire, and Dutch strains on Nov 20

Progress —Shortly after admission her temperature rose to 104 6°F, the respiration-rate increased to 44 a minute, and her condition became critical She was treated with parenteral cortisone (50 mg six-hourly) and penicillin (1 million units six-hourly) Within four hours some clinical improvement was apparent Next day her pupils reacted sluggishly to light but there was otherwise no change in her condition Her attitude was one of decerebrate rigidity, with the upper limbs medially rotated at the shoulder joints, extended at the elbows and hyperpronated, the legs were held in extension with the feet plantar-flexed On Nov 23 she began to respond to painful stimuli, and to exhibit alternating phases of rigidity and flaccidity She remained pyrexial but the respiration-rate was less rapid On Nov 25, after six days in coma, she recovered consciousness rapidly and was able to recognise her parents She was then noted to have a foot-drop on the left, with complete paralysis of the extensors and peronei, and an area of sensory impairment to pin-prick over the dorsum of the foot This was thought to be due to compression of the lateral popliteal nerve Otherwise her recovery was uneventful When seen recently, however, she complained that writing was difficult and her script had changed in character

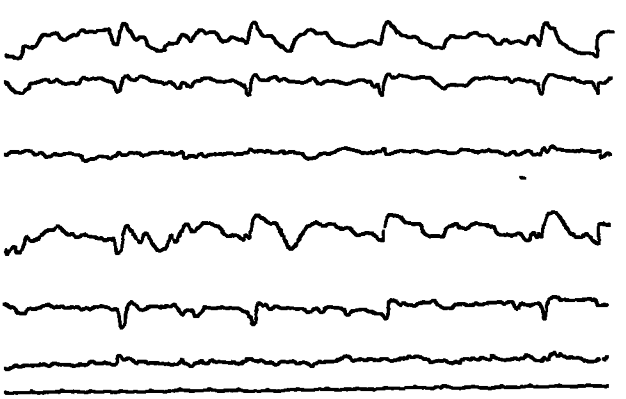

Fig 2—Case 2 electroencephalogram, Nov 21 Electrode positions as in fig 1

The Family —The mother, father, and 2 children other than cases 1 and 2 all had febrile illnesses diagnosed as Asian influenza Complement-fixation tests were done on three who were not admitted The results were:

	Date	*Complement-fixation (influenza A)*	*Hæmagglutination inhibitions* (Asian)	(Scan-	(Eire)	(Dutch)
Father	Nov 25	1/32	1/64	<1/16	<1/8	<1/8
	Dec 5	1/16	1/64	<1/16	<1/8	<1/8
Mother	Nov 25	1/128	1/64	<1/8	<1/16	<1/8
Daughter	Nov 27	1/128	1/128	<1/32	<1/16	<1/4

This daughter had an episode of drowsiness and headache four or five days after the febrile illness, but recovered without treatment

These results, and those of cases 1 and 2, indicate recent infection with influenza A (Asian)

Case 3 —A woman, aged 32, was admitted to the Cardiff Royal Infirmary on Nov 26, 1957 On Oct 26 she had a short illness of three days, with aching limbs, coryza, and slight cough This was thought to be influenza On Nov 1 blurring of vision, diplopia, and occasional vomiting developed Three days later she was admitted to a local hospital, where she was found to have a loss of vertical conjugate gaze and blurring of the disc edges, and the right knee and ankle jerks were more brisk than those on the left At lumbar puncture, the fluid was clear and colourless and under a pressure of 160 mm H_2O It contained no cells, and the protein content was 30 mg per 100 ml

She was transferred to the Cardiff Royal Infirmary on Nov 26, 1957, for further investigation, but by now felt perfectly well She was alert The pupils were dilated, the right more than the left, and the reaction to light was very sluggish on both sides The pupil response to convergence was impaired, and there was limitation of conjugate upward gaze The rest of the cranial nerves were normal There were no abnormal neurological signs in the upper or lower limbs, and no other abnormal physical signs were demonstrated

Investigations —Cerebrospinal fluid (C S F) under normal pressure cells 5 per c mm , protein 37 mg per 100 ml , chloride 127 mEq per litre Blood and C S F Wasserman and Kahn tests negative Blood-count normal An electroencephalogram on Nov 27 was within normal limits

Complement-fixing antibodies for influenza A were present at a titre of 1/64 (Nov 27) and 1/64 (Dec 5) By hæmagglutination inhibition the titre was 1/128 for the Asian variety and less than 1/16 for the Scandinavian, Eire, and Dutch strains, indicating a recent infection with influenza A (Asian)

Progress —While she was in hospital the diplopia cleared up completely A lumbar air encephalogram failed to reveal any abnormality She was discharged home on Dec 9, 1957

Case 4.—A girl, aged 6 years, was taken ill on Oct 23, 1957, with headache and fever Next day she felt better but was thought to have a cold On Oct 26 she was listless and reluctant to play She was, however, well enough to travel to Cardiff next day During the journey she began to vomit and this persisted, with pain in the back of the neck, until she was admitted to a local hospital on Oct 30 Here she was found to be drowsy but easily rousable, cooperative, and normally oriented Temperature 100 2°F, pulse-rate 110, respiration-rate 26 a minute There was a slight increase in tone and reflexes in all four limbs The plantar responses were equivocal Signs of meningeal irritation were present Lumbar puncture produced a fluid containing 80 lymphocytes per c.mm. and an increased amount of globulin

Next day she was more drowsy, the tone and reflexes in the right arm and leg were exaggerated, and the right plantar response was extensor She was transferred to the Cardiff Royal Infirmary on Nov 1 She was very drowsy, but could be roused by painful stimuli Speech was limited to the word "yes", and she did not seem to understand simple instructions Neck rigidity was present, but Kernig's sign was negative Temperature, pulse-rate, and respiration-rate were normal No abnormality was demonstrated in the cranial nerves The limbs were hypotonic There was slight weakness of the right arm and leg, the tendon reflexes on the right were slightly more brisk than those on the left The right plantar response was extensor The abdominal reflexes were not altered. No other abnormal neurological signs were detected, and the other systems were normal

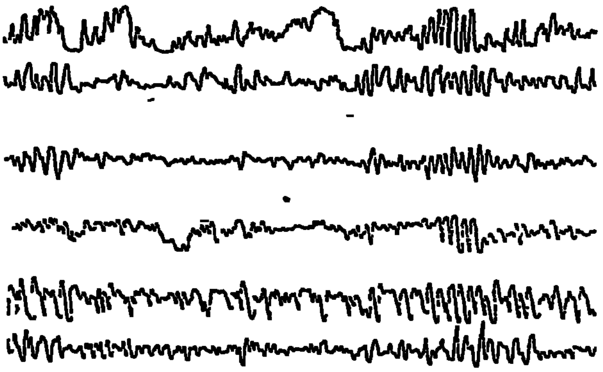

Fig 3—Case 4 electroencephalogram, Oct. 24 Electrode positions as in fig 1

Investigations —Shortly after admission the lumbar puncture was repeated pressure 55 mm H_2O, 68 lymphocytes per c.mm , protein 54 mg per 100 ml

Blood-count normal Radiographs of skull and chest normal

The electroencephalogram on the day after admission showed intermittent runs of high-voltage smooth delta waves at about 3 cycles a second in all leads A wide range of moderately high-voltage theta waves also occurred There was no subdelta or focal activity (fig 3) Complement-fixation tests gave the following titres

Date	*Complement fixation*			
	Influenza A	*Influenza C*	*Mumps*	
			S	*V*
Nov 1	1/64	1/64	1/8	1/64
Nov 4	1/64	1/64	1/8	1/64
Nov 18	1/32	1/64	1/8	1/64
Nov 27	1/64	1/32	1/8	1/32

By hæmagglutination inhibition the titre was 1/32 for the Asian variety on 3 occasions and 1/16 on Nov 18. It was less than 1/8 for the Scandinavian, Eire, and Dutch strains These figures are consistent with fairly recent infection by influenza A (Asian) virus It is likely that the febrile illness was Asian influenza, but influenza C and mumps cannot be excluded

Lumbar punctures were performed daily for four days and then at increasing intervals The cell-count rose to 1300 per c.mm on the third day after admission and then dropped steadily to 5 per c.mm on the eighteenth day At the height of the pleocytosis there was a preponderance of polymorphs, but thereafter the proportion of lymphocytes steadily increased from 60% to 90% of the total cell-count On Nov 28 the cell-count was normal The protein content varied between 40 and 80 mg per 100 ml and the sugar between 50 and 75 mg per 100 ml, and the chloride remained at about 130 mEq per litre

Progress —A provisional diagnosis of meningitis was made and she was treated with penicillin The diagnosis, however, was revised to one of encephalitis in view of the cerebrospinal-fluid findings By Nov 5 she was greatly improved and mentally alert and cooperative Speech was normal except for a nasal quality, which her parents said was normal No abnormal neurological signs could be found except for slight neck rigidity She was discharged from hospital on Nov 28 The electroencephalogram on that day showed a very great improvement.

Discussion

In all these patients neurological involvement followed four or five days after the onset of a febrile illness That this febrile illness was Asian influenza appears to have been established by the results of the complement-fixation tests in 3 cases The high infectivity of the disease is shown by its spread in the family of the first 2 cases, for the other 4 members of this family had febrile illnesses, and blood from 3 showed evidence of recent infection with influenza A (Asian) Blood was not obtained from the 4th member The daughter whose blood was examined also had involvement of the nervous system following her attack of influenza She complained of severe headache and became drowsy, but recovery was uneventful Case 4 had an illness very like lymphocytic choriomeningitis, and was the only one in whom a cell response developed in the cerebrospinal fluid The illness followed what was thought to be Asian influenza, and although the results of the complement-fixation tests do not altogether exclude influenza C and mumps, we believe that the neurological disorder in this case, as in the others, followed Asian influenza.

3 of the patients (cases 1, 2, and 4) were very ill and caused some anxiety, but when recovery began it was rapid and apparently complete In cases 1 and 2 the electroencephalogram, although grossly abnormal at the height of the illness, soon reverted to normal It has since been reported that the handwriting of case 2 has deteriorated, and this is probably evidence that recovery has not been as complete as was at first thought.

Summary

In 4 patients severe disorders of the nervous system followed a short febrile illness 3 of the patients had encephalitis and 1 had an illness resembling lymphocytic choriomeningitis In all of them complement-fixation tests showed evidence of a recent infection with influenza A (Asian), but in one the antibody titres for influenza C and mumps were also raised

We wish to thank Dr Idris G Jones and Mr Charles Langmaid, under whom the patients were admitted, and Dr J D Spillane for helpful criticism We are also indebted to Dr A D Evans, of the Public Health Laboratory Service, who carried out and advised us about the complement-fixation tests, and to Mr R. Marshall for the photographs

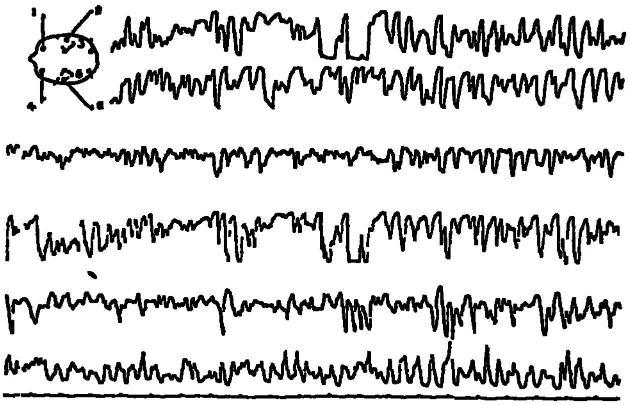

Fig 1—Case 1 electroencephalogram, Nov 21

had been taken ill at the same time as her brother and her illness followed the same course She became drowsy on Nov 18 and next morning was semicomatose She was admitted to a local hospital in coma and was transferred to the Cardiff Royal Infirmary next day

She was in deep coma There were no involuntary movements Temperature 101 6°F, pulse-rate 100, respiration-rate 35 a minute The pupils were dilated and fixed to light The fundi were normal The limbs were flaccid with symmetrically diminished tendon reflexes Both plantar responses were extensor There was no response to painful stimuli No abnormal signs were detected in the cardiovascular or respiratory systems

Investigations—Lumbar puncture on the day of admission produced a clear colourless fluid under a pressure of 90 mm H_2O cells < 5 per c mm, protein 39 mg per 100 ml, chloride 124 mEq per litre, sugar 99 mg per 100 ml

Hb 15 5 g per 100 ml, leucocyte-count 11,800 per c mm (91% polymorphs) Platelet-count on Nov 25, 65,000 per c mm, Dec 5, normal A radiograph of the chest revealed no abnormality

An electroencephalogram (Nov 21) showed a grossly abnormal record The tracing was very flat, but occasional slow subdelta waves occurred exhibiting bilateral frontal predominance During part of the record the slow activity showed a definite periodicity (fig 2) A further electroencephalogram on Nov 27 was normal

The titre of complement-fixing antibodies for influenza A was 1/2408 (Nov 20), 1/128 (Dec 2) and 1/64 (Dec 5) By hæmagglutination inhibition the titre was 1/480 for the Asian variety and less than 1/4 for the Scandinavian, Eire, and Dutch strains on Nov 20

Progress—Shortly after admission her temperature rose to 104·6°F, the respiration-rate increased to 44 a minute, and her condition became critical She was treated with parenteral cortisone (50 mg six-hourly) and penicillin (1 million units six-hourly) Within four hours some clinical improvement was apparent Next day her pupils reacted sluggishly to light but there was otherwise no change in her condition Her attitude was one of decerebrate rigidity, with the upper limbs medially rotated at the shoulder joints, extended at the elbows and hyperpronated, the legs were held in extension with the feet plantar-flexed On Nov 23 she began to respond to painful stimuli, and to exhibit alternating phases of rigidity and flaccidity She remained pyrexial but the respiration-rate was less rapid On Nov 25, after six days in coma, she recovered consciousness rapidly and was able to recognise her parents She was then noted to have a foot-drop on the left, with complete paralysis of the extensors and peronei, and an area of sensory impairment to pin-prick over the dorsum of the foot This was thought to be due to compression of the lateral popliteal nerve Otherwise her recovery was uneventful When seen recently, however, she complained that writing was difficult and her script had changed in character

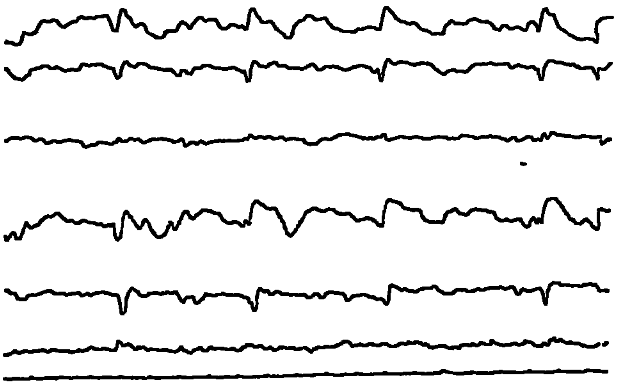

Fig 2—Case 2 electroencephalogram, Nov 21 Electrode positions as in fig 1

The Family—The mother, father, and 2 children other than cases 1 and 2 all had febrile illnesses diagnosed as Asian influenza Complement-fixation tests were done on three who were not admitted The results were

	Date	*Complement-fixation (influenza A)*	*Hæmagglutination inhibitions* (Asian)	(Scan-	(Eire)	(Dutch)
Father	Nov 25	1/32	1/64	<1/16	<1/8	<1/8
	Dec 5	1/16	1/64	<1/16	<1/8	<1/8
Mother	Nov 25	1/128	1/64	<1/8	<1/16	<1/8
Daughter	Nov 27	1/128	1/128	<1/32	<1/16	<1/4

This daughter had an episode of drowsiness and headache four or five days after the febrile illness, but recovered without treatment

These results, and those of cases 1 and 2, indicate recent infection with influenza A (Asian)

Case 3—A woman, aged 32, was admitted to the Cardiff Royal Infirmary on Nov 26, 1957 On Oct 26 she had a short illness of three days, with aching limbs, coryza, and slight cough This was thought to be influenza On Nov 1 blurring of vision, diplopia, and occasional vomiting developed Three days later she was admitted to a local hospital, where she was found to have a loss of vertical conjugate gaze and blurring of the disc edges, and the right knee and ankle jerks were more brisk than those on the left At lumbar puncture, the fluid was clear and colourless and under a pressure of 160 mm H_2O It contained no cells, and the protein content was 30 mg per 100 ml

She was transferred to the Cardiff Royal Infirmary on Nov 26, 1957, for further investigation, but by now felt perfectly well She was alert The pupils were dilated, the right more than the left, and the reaction to light was very sluggish on both sides The pupil response to convergence was impaired, and there was limitation of conjugate upward gaze The rest of the cranial nerves were normal There were no abnormal neurological signs in the upper or lower limbs, and no other abnormal physical signs were demonstrated

Investigations—Cerebrospinal fluid (C S F) under normal pressure cells 5 per c mm, protein 37 mg per 100 ml, chloride 127 mEq per litre Blood and C S F Wasserman and Kahn tests negative Blood-count normal An electroencephalogram on Nov 27 was within normal limits

Complement-fixing antibodies for influenza A were present at a titre of 1/64 (Nov 27) and 1/64 (Dec 5) By hæmagglutination inhibition the titre was 1/128 for the Asian variety and less than 1/16 for the Scandinavian, Eire, and Dutch strains, indicating a recent infection with influenza A (Asian)

Progress—While she was in hospital the diplopia cleared up completely A lumbar air encephalogram failed to reveal any abnormality She was discharged home on Dec 9, 1957

Case 4—A girl, aged 6 years, was taken ill on Oct 23, 1957, with headache and fever Next day she felt better but was thought to have a cold. On Oct. 26 she was listless and reluctant to play. She was, however, well enough to travel to Cardiff next day. During the journey she began to vomit and this persisted, with pain in the back of the neck, until she was admitted to a local hospital on Oct. 30. Here she was found to be drowsy but easily rousable, cooperative, and normally oriented. Temperature 100.2°F, pulse-rate 110, respiration-rate 26 a minute. There was a slight increase in tone and reflexes in all four limbs. The plantar responses were equivocal. Signs of meningeal irritation were present. Lumbar puncture produced a fluid containing 80 lymphocytes per c.mm. and an increased amount of globulin.

Next day she was more drowsy, the tone and reflexes in the right arm and leg were exaggerated, and the right plantar response was extensor. She was transferred to the Cardiff Royal Infirmary on Nov. 1. She was very drowsy, but could be roused by painful stimuli. Speech was limited to the word " yes ", and she did not seem to understand simple instructions. Neck rigidity was present, but Kernig's sign was negative. Temperature, pulse-rate, and respiration-rate were normal. No abnormality was demonstrated in the cranial nerves. The limbs were hypotonic. There was slight weakness of the right arm and leg, the tendon reflexes on the right were slightly more brisk than those on the left. The right plantar response was extensor. The abdominal reflexes were not altered. No other abnormal neurological signs were detected, and the other systems were normal.

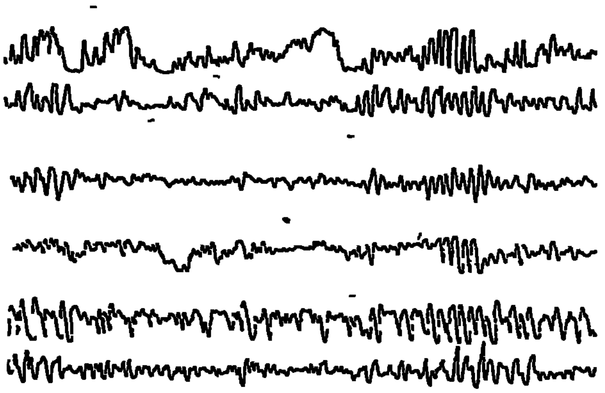

Fig 3—Case 4 electroencephalogram, Oct. 24. Electrode positions as in fig 1.

Investigations.—Shortly after admission the lumbar puncture was repeated: pressure 55 mm. H_2O, 68 lymphocytes per c.mm., protein 54 mg. per 100 ml.

Blood-count normal. Radiographs of skull and chest normal.

The electroencephalogram on the day after admission showed intermittent runs of high-voltage smooth delta waves at about 3 cycles a second in all leads. A wide range of moderately high-voltage theta waves also occurred. There was no subdelta or focal activity (fig. 3). Complement-fixation tests gave the following titres:

Date	*Complement fixation*			
	Influenza A	*Influenza C*	*Mumps*	
			S	*V*
Nov. 1	1/64	1/64	1/8	1/64
Nov. 4	1/64	1/64	1/8	1/64
Nov. 18	1/32	1/64	1/8	1/64
Nov. 27	1/64	1/32	1/8	1/32

By hæmagglutination inhibition the titre was 1/32 for the Asian variety on 3 occasions and 1/16 on Nov. 18. It was less than 1/8 for the Scandinavian, Eire, and Dutch strains. These figures are consistent with fairly recent infection by influenza A (Asian) virus. It is likely that the febrile illness was Asian influenza, but influenza C and mumps cannot be excluded.

Lumbar punctures were performed daily for four days and then at increasing intervals. The cell-count rose to 1300 per c.mm. on the third day after admission and then dropped steadily to 5 per c.mm. on the eighteenth day. At the height of the pleocytosis there was a preponderance of polymorphs, but thereafter the proportion of lymphocytes steadily increased from 60% to 90% of the total cell-count. On Nov. 28 the cell-count was normal. The protein content varied between 40 and 80 mg. per 100 ml. and the sugar between 50 and 75 mg. per 100 ml., and the chloride remained at about 130 mEq per litre.

Progress.—A provisional diagnosis of meningitis was made and she was treated with penicillin. The diagnosis, however, was revised to one of encephalitis in view of the cerebrospinal-fluid findings. By Nov. 5 she was greatly improved and mentally alert and cooperative. Speech was normal except for a nasal quality, which her parents said was normal. No abnormal neurological signs could be found except for slight neck rigidity. She was discharged from hospital on Nov. 28. The electroencephalogram on that day showed a very great improvement.

Discussion

In all these patients neurological involvement followed four or five days after the onset of a febrile illness. That this febrile illness was Asian influenza appears to have been established by the results of the complement-fixation tests in 3 cases. The high infectivity of the disease is shown by its spread in the family of the first 2 cases, for the other 4 members of this family had febrile illnesses, and blood from 3 showed evidence of recent infection with influenza A (Asian). Blood was not obtained from the 4th member. The daughter whose blood was examined also had involvement of the nervous system following her attack of influenza. She complained of severe headache and became drowsy, but recovery was uneventful. Case 4 had an illness very like lymphocytic choriomeningitis, and was the only one in whom a cell response developed in the cerebrospinal fluid. The illness followed what was thought to be Asian influenza, and although the results of the complement-fixation tests do not altogether exclude influenza C and mumps, we believe that the neurological disorder in this case, as in the others, followed Asian influenza.

3 of the patients (cases 1, 2, and 4) were very ill and caused some anxiety, but when recovery began it was rapid and apparently complete. In cases 1 and 2 the electroencephalogram, although grossly abnormal at the height of the illness, soon reverted to normal. It has since been reported that the handwriting of case 2 has deteriorated, and this is probably evidence that recovery has not been as complete as was at first thought.

Summary

In 4 patients severe disorders of the nervous system followed a short febrile illness. 3 of the patients had encephalitis and 1 had an illness resembling lymphocytic choriomeningitis. In all of them complement-fixation tests showed evidence of a recent infection with influenza A (Asian), but in one the antibody titres for influenza C and mumps were also raised.

We wish to thank Dr. Idris G. Jones and Mr. Charles Langmaid, under whom the patients were admitted, and Dr. J. D. Spillane for helpful criticism. We are also indebted to Dr. A. D. Evans, of the Public Health Laboratory Service, who carried out and advised us about the complement-fixation tests, and to Mr. R. Marshall for the photographs.

ACUTE PSYCHOSES DUE TO ENCEPHALITIS FOLLOWING ASIAN INFLUENZA

E Bental
M D Jerusalem

JUNIOR REGISTRAR, DEPARTMENT OF NERVOUS DISEASES,
ROTHSCHILD-HADASSAH-UNIVERSITY HOSPITAL AND
HEBREW UNIVERSITY-HADASSAH MEDICAL SCHOOL

THERE have been three great influenza pandemics in e past seventy years, and after each of them various omplications have been reported pneumonia and myoarditis, first described by Leichtenstern in 1896 (Lyon 956), encephalitis (Leichtenstern 1890, Pfuhl 1892), and sychoses (Rorie 1901) In the influenza epidemic in erusalem in 1957 we encountered acute psychotic anifestations in three children

Case-reports

Case 1 —A boy, aged 15, was admitted on Sept 25, 1957, an acute state of confusion, anxiety, and restlessness He ied and clung to his mother, claiming that she wanted to ave him His parents related that, a week before, the boy had omplained of severe frontal headaches In spite of this he ontinued to attend school until two days before admission, hen he suddenly left school before the end of lessons, apparntly owing to an argument with his teacher He was very stless when he came home and begged his mother to protect m from his teacher and not to abandon him On the eve of s admission he suddenly tried to strangle his mother

On examination no general or neurological abnormalities ere found The boy was in a state of great tension and kept s eyes closed all the time, claiming that his mother had rbidden him to open them He begged continuously for his other so that he might suck milk from her, expressing that me wish to every nurse who entered his room He masrbated for hours and wet his bed He refused food of any nd No contact could be established with him

Treatment and progress —Because of his extreme restlessness e was kept under constant sedative and tranquillising treatent During the first five days he had slight pyrexia, which se only once to 103 1°F On the second day after admission rced grasping of his left hand was noticed The first impreson was that the boy had acute hysteria probably connected ith the argument at school with his teacher The forced rasping which appeared later seemed to indicate an organic asis to his illness Further support for this assumption was rovided by electroencephalography the record was grossly bnormal, with generalised slow activity of the delta range, ith high amplitude mainly localised in the posterior regions f the brain (fig 1) Repeated electroencephalography during the next eight days, showed similar diffuse abnormal patterns Other investigations, including radiography of his skull and chest and chemical analysis of his blood and cerebrospinal fluid (C S F) were normal On the sixth day in hospital the boy grew calmer His whole appearance changed, he became quiet, shy, and well behaved He dressed neatly and ate normally His orientation in time and place was good, but he remembered nothing of his illness A fortnight after the onset he was back at school, a composed pleasant boy without any abnormal behaviour

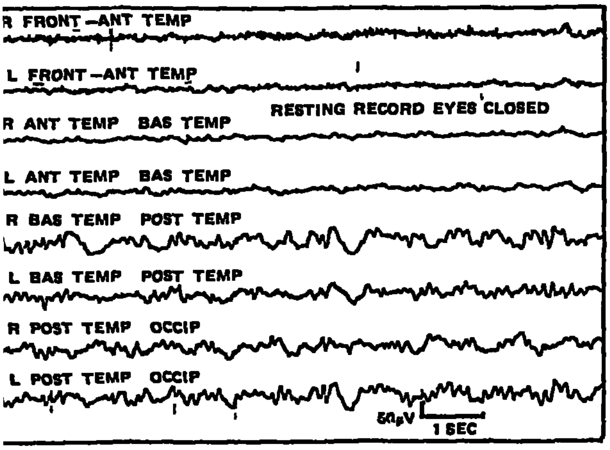

Fig 1—Case 1 resting electroencephalogram

Follow-up —Repeated electroencephalography in the three months following his discharge showed a clear improvement, although the records were still moderately abnormal, with diffuse theta activity (fig 2) Only sporadic cases of Asian influenza had been reported in Jerusalem at the time of the boy's illness, so we did not relate this acute psychotic reaction to influenza A later epidemiological investigation revealed, however, that all six members of the boy's family had had Asian influenza after he had been admitted to hospital Moreover influenza had already been reported among his neighbours three days before the onset of his illness In view of this a sample of his blood was sent to be tested for hæmagglutinin inhibition of influenza virus A/Singapore/1/57, and a titre of 1 382 was found, proving that the boy had had Asian influenza before his acute psychosis

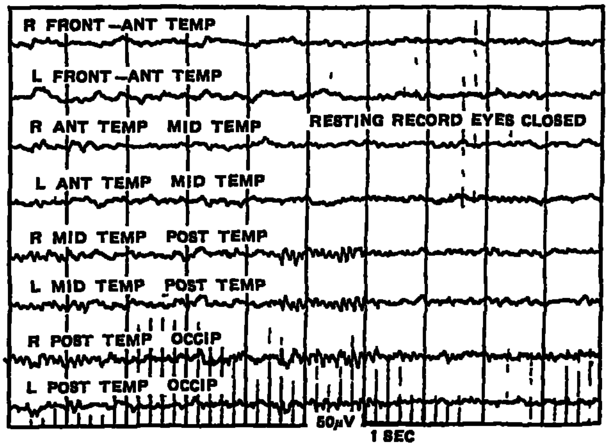

Fig 2—Case 1 resting electroencephalogram three months after discharge

Case 2 —A girl, aged 11½ years, had been ill for ten days In the family all four children as well as the mother had had a febrile disease which had been diagnosed as Asian influenza After recovery the girl attended school again, but after a week she returned from school complaining of headaches She lay in bed for twenty-four hours in almost complete apathy Then suddenly she became very restless, got out of bed, ran about the house, and went to neighbours, telling them that her father had killed her mother, and that she was left alone The girl complained that she was being followed all the time by a woman who was trying to catch her She presented a picture of acute anxiety and was brought to the hospital in that condition

On admission physical and neurological examination and lumbar puncture did not reveal any abnormalities The blood-count was normal, and the erythrocyte-sedimentation rate (E S R) was 50 mm in the first hour (Westergreen) Electrocardiography gave a normal tracing Radiography of the skull was normal, but radiography of the chest showed a slight shadowing in the inner part of the lower left lung and, to a lesser degree, on the right side too On the basis of this finding viral pneumonia was diagnosed The titre for influenza virus A/Singapore/1 57 was 1 384 Electroencephalography gave a very abnormal record with generalised slow theta and delta

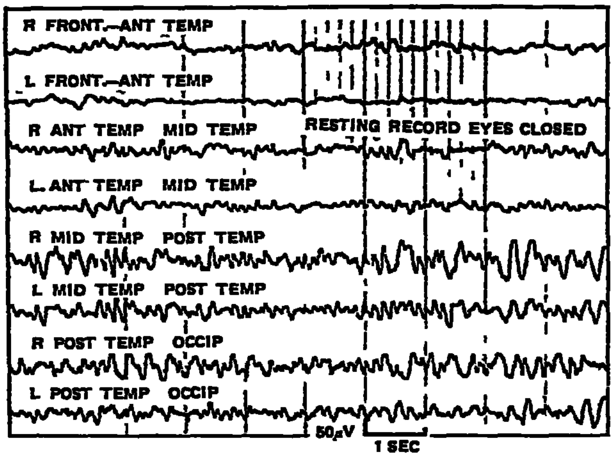

Fig 3—Case 2 resting electroencephalogram

activity (fig 3). During photic stimulation bursts of slow waves and spikes appeared, especially on closure of the eyes (fig 4). Contact was most difficult to establish with the girl. She remained silent most of the time. Occasionally she would wander about the department looking absolutely lost. At times she would cry and yell for hours for no apparent reason. After four days she gradually calmed down and recognised people, especially her family. She remembered nothing of her illness. A radiograph of her chest before her discharge was normal. After a fortnight she returned to normal life, feeling quite well.

Follow-up.—Repeated electroencephalography after her discharge showed a gradual improvement, although the tracings were still abnormal, with diffuse theta activity and sporadic spiky activity during photic stimulation.

Case 3.—A boy, aged 9½ years, brother of case 2, was admitted on Nov. 20, 1957. Three weeks earlier he had been ill, together with other members of his family. During the last two days of his illness he was very restless, got out of bed, moved around aimlessly, and mumbled only incomprehensible words. Although he was known to be mildly retarded, attending a special school for such children, his mother found his behaviour unusually strange and abnormal during his illness. These signs disappeared gradually in two or three days. He became quiet again, went back to school, and for a week was well. Ten days after his recovery he suddenly returned from school before the end of lessons, complaining of severe headache and general malaise. At that time his orientation in time and place was still good. He was put to bed. During the next two days he again became restless, cried, and shouted. He complained that somebody was trying to catch and beat him. He was in an extreme state of tension and anxiety and apparently had fears and hallucinations. In this condition he was admitted to hospital.

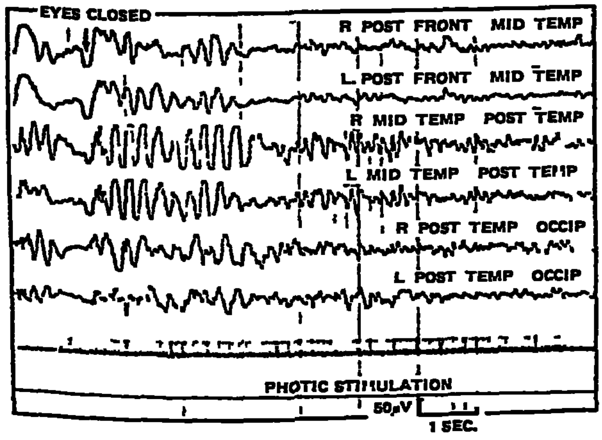

Fig 4—Case 2 electroencephalogram during photic stimulation

On admission physical and neurological examination, radiography of his skull and chest, and routine laboratory examinations revealed no abnormal findings. Culture of his C.S.F. for influenza virus was negative. His blood titre for influenza virus was 1 192. Electroencephalography gave a diffusely disturbed record with increased theta and delta activity, mainly in the posterior regions of the brain (fig 5). This confirmed the tentative diagnosis of an organic psychosis in connection with the influenza. Electrocardiography gave an abnormal record with S-T depression in L2 and L3 with T waves of low voltage. On the basis of this finding postinfluenzal myocarditis was also considered.

Progress.—Within ten days the boy calmed down. His whole expression changed, becoming serene, with no signs of fright or anxiety any longer. He started to become oriented in time and place but could not recall what had happened to him, or how he had come to be in hospital. Repeated electroencephalography still gave diffusely abnormal tracings. Electrocardiography seven days later was again abnormal, showing notched T waves in V_3 and V_4. Electrocardiography a week later still was within normal limits. The boy was discharged after a fortnight. He went back to school, but after ten days he apparently had a relapse of the psychotic reaction and was readmitted in a state similar to that described above, characterised by restlessness and anxiety.

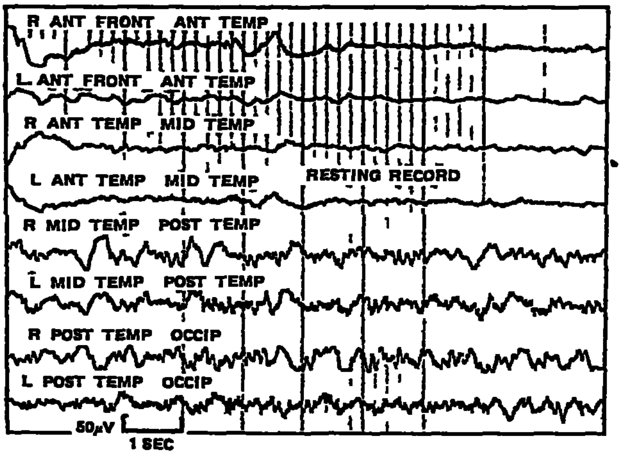

Fig 5—Case 3 resting electroencephalogram

On readmission physical examination revealed wet rales over both his lungs. A grade-II systolic murmur was heard over the base of his heart. His pulse-rate was 120, blood-pressure 120,80 mm. Hg, and liver slightly enlarged. Neurological examination revealed no abnormalities. The E.S.R. was 19 mm. in the first hour (Westergreen). The titre of influenza virus A/Singapore/1/57 hæmagglutinin inhibition in the blood was 1 383—much higher than during his first stay in hospital. Radiography of his chest showed an enlarged hilum of the left lung and patchy shadows at the base of both lungs. Electroencephalography gave a most abnormal record, worse than on the first stay in hospital, showing much theta and delta activity. Electrocardiography showed inverted T waves in V_3 and V_4 and a prominent R wave in aVR, this being a significant change in comparison with the previous electrocardiograms, indicating right ventricular strain and myocardial damage.

Treatment was started immediately with antibiotics, digitalin, and sedatives. At the end of a week the boy recovered from the acute psychotic state and became calm and well oriented again.

Follow-up electrocardiography, although showing an improvement, was still abnormal, with notched T waves in V_2 and V_3

Discussion

All three patients developed psychotic manifestations from two to ten days after the onset of Asian influenza These manifestations were almost identical in all the cases, including signs of acute anxiety, confusion, extreme restlessness, and ideas of persecution The acute psychotic symptoms receded within the relatively short period of from six to eight days, leaving the patients with complete amnesia about what had happened to them during the acute stage of the illness These three patients were children aged less than 16 Another feature common to all the cases was the diffusely abnormal electroencephalograms which remained abnormal long after the clinical recovery of the patients

The appearance of acute psychotic states after influenza has been a well-established fact ever since the great influenza pandemic of 1899–1900 (Dillon 1909, Rouge 1909, Graves 1928, Bartstra and Pesman 1950) The manifestations described were manifold and included depressions, manic conditions, amentias, acute delirious states, hysterical reactions, ideas of persecution, and hallucinations (Rorie 1901, Jelliffe 1918) At the beginning of the century some workers argued for and against a direct connection between such psychotic manifestations and influenza Klemm (1901) rejected the idea of "specific" influenzal psychoses, claiming that, in some patients at least, the psychosis was latent and only activated by the influenza Other workers suggested bacteriological examinations as a means of correlating the onset of the psychosis with the influenza Thus Neumann (1914) suggested that the influenza microbe (*Hæmophilus influenzæ*) should be isolated from the C S F by culture on pigeon's blood-agar In case 3 the striking rise in titre of the influenza virus hæmagglutinin inhibition found during the boy's second psychotic outbreak provided immunological proof of a correlation between the activity of the influenza virus and the psychosis Another bridge between these psychotic manifestations and the Asian influenza in the present cases was provided by electroencephalography, which revealed an abnormal pattern The diffuse abnormal electrical activity of the brain in these patients supported the diagnosis of postinfluenzal encephalitis, whose only clinical manifestation was the acute psychosis

Summary

Acute psychosis came on after Asian influenza in three children

In all three cases diffuse abnormal electrical activity of the brain was recorded

The acute psychosis was apparently the only clinical manifestation of encephalitis

Clinical remission occurred in a relatively short time, appearing much earlier than normal electroencephalograms

I wish to thank Prof L Halpern for his most helpful criticism and advice

PSYCHOSIS FOLLOWING ASIAN INFLUENZA IN BARBADOS

R M Lloyd Still
O B E, M R C S
MEDICAL SUPERINTENDENT, MENTAL HOSPITAL, BARBADOS, B W I

"Asian" influenza* was first reported in Barbados on Sept 14, 1957, and in the five weeks from Sept 25 to Oct 31 no fewer than nineteen cases of psychosis definitely attributable to it were admitted to the Mental Hospital Fourteen gave a clear history of influenza preceding their mental breakdown, and some of these were admitted while still pyrexial

Fourteen of the patients were women and five were men, their ages ranged from 15 to 67 (average 28, median 24) Most of them were restless, noisy, resistive, and disoriented, and some were untidy and faulty in habits Seven had hallucinations, and four of these were rational and well-behaved in contrast to the general excitement and confusion shown by the rest of the group These seven all complained of a strange unpleasant smell but could not describe it clearly

> "Unlike anything I know"
> "Unpleasant smell which I can't describe"
> "Like a dead smell"

These patients had no such difficulty in describing their visual and auditory hallucinations

Illustrative Case-reports

Case 10 A woman, aged 26, *was admitted from the* General Hospital with a temperature of 100 6° She was restless, resistive, noisy, and obscenely abusive, and she refused to wear any clothes She improved rapidly on electroconvulsion therapy (E C T) and was discharged on trial after 21 days

Case 2—A girl, aged 16, was restless, noisy, talkative and abusive She gave a hisory of having had influenza recently She was given E C T but made only slow progress, gradually becoming less hyperactive and abusive She was discharged on trial after 59 days

Case 18—A man, aged 36, was quiet, well behaved, well oriented, and rational in speech, but had striking aural, visual, and olfactory hallucinations He saw large and small spirits, *with no clothes on and experienced a sweet smell which he* was unable to describe and was unlike anything he knew His blood Kahn test was positive but his cerebrospinal fluid Kahn and colloidal-gold tests were negative

He improved rapidly on E C T and was discharged on trial after 24 days

Case 17—A man, aged 25, was rational and well oriented, but had aural, visual, and olfactory hallucinations He saw animals at the windows, and complained of a filthy smell, but appeared to realise that these phenomena were not real Two *days after admission he became violent and attacked the* nurses, under the delusion that he was a gorilla His mother and father had both been discharged from the mental hospital earlier in the year, the mother with a hallucinatory syndrome, and the father with an alcoholic confusional psychosis He recovered rapidly with E C T and was discharged on trial after 26 days

The toxic psychosis, whether primarily confusional or hallucinatory, cleared up rapidly Four patients had no specific treatment, and fifteen were given a short course of electro-convulsion therapy, two of the fifteen had insulin as well Within 17 weeks all had been discharged, with an average hospital stay of 38 days

---

*Though the diagnosis was not confirmed by virological methods, the outbreak coincided with others, in neighbouring areas, which were thus confirmed Epidemiologically the outbreak—explosive and widespread—*was not at all like the influenza to which we have been accustomed in Barbados*

Comment

It is impossible to give the incidence of toxic psychosis following Asian influenza in Barbados, because the epidemic, though widespread, was not severe, and many of those affected (among the population of about 230,000) did not consult their doctors Moreover, it appears that some patients with mental symptoms following influenza were successfully treated at home by the family doctor The presence of psychosis could not be correlated with the severity of the febrile attack, most of the affected patients were incapable of giving any history about their confusional state, and their relatives were of little help In the two cases where the patient had previously been in the Mental Hospital the influenzal attack may be regarded as merely precipitating a relapse

Summary

A toxic psychosis was seen in 19 patients in Barbados shortly after (or towards the end of) an attack of Asian influenza Most were young adults

15 patients had electroconvulsion therapy and 2 insulin as well 4 had no treatment All recovered rapidly

7 patients presented an unusual hallucinatory syndrome, in which bizarre smells were often experienced

I wish to thank Dr R A Webb for his assistance in compiling this report, and Dr M A Byer, director of medical services, for permission to publish it

HEPARINISED BLOOD FOR EXCHANGE TRANSFUSION

G H Valentine

M B Brist, M R C P, F R C P (C), D C H

PÆDIATRICIAN, ST THOMAS ELGIN GENERAL HOSPITAL, ST THOMAS, LECTURER IN PÆDIATRICS, UNIVERSITY OF WESTERN ONTARIO, CANADA

In blood-transfusion the use of citrate as the anticoagulant has become almost traditional For most purposes it is entirely satisfactory, and it has the advantage that blood treated with suitable citrate-dextrose mixtures can be kept long enough to be held in stock against an emergency However, the work of Firt and Hejhal (1957), on the toxicity of citrated blood given in large rapid transfusions raises the question of whether it is ideal for exchange transfusions in the newborn The sudden collapse seen occasionally during exchange transfusion could be due to citrate intoxication

In other respects citrated blood may not be ideal for exchange transfusion The addition of acid-citrate-dextrose mixtures lowers the hæmoglobin content of the donor blood by simple dilution, and can lead to expansion of the red cell by as much as 20% (Mollison 1951) If the cells shrink to normal size after they are transfused, the patient receives, in effect, a transfusion of blood with a low packed-cell volume Neither of these effects is desired

The removal of part of the supernatant citrated plasma after sedimentation of the red cells would cancel both the dilution of the donor blood and the expansion of the red cells, and would lessen the likelihood of citrate intoxication the use of sedimented erythrocytes for exchange transfusion is recommended by Sisson et al (1958) But it is more rational to use some other anticoagulant Experience with heparinised blood is here recorded

Material and Method

In 1948–54 I had personal experience of about 70 exchange transfusions in English hospitals, using citrated blood The records are not readily available, but there were several cases of severe shock, which appeared to be due to acute heart-failure This developed towards the end of the transfusion and was common enough to make one approach exchange transfusion with some apprehension 3 babies died The same syndrome was observed in Canada in 1954–55 when citrated blood was used, though the exchanges were done slowly with 10ml aliquots, a blood-volume deficit was maintained, frequent halts were observed during the exchange, and calcium gluconate was given at each 100 ml of the exchange

In November, 1955, I began to use heparinised blood in an attempt to avoid this syndrome, and I have not used citrated blood since 21 exchange transfusions have been performed 9 babies with rhesus hæmolytic disease received 13 exchange transfusions, 5 with ABO incompatibility disease received 7, and 1 with severe "physiological" jaundice was given 1 This last, aged 12 days, was transfused through the saphenous vein at the groin, but in the remainder the umbilical vein was used

The indications for exchange transfusion, in a baby with rhesus hæmolytic disease, have been

1 A birth-weight under $5^1/_2$ lb
2 A cord-blood hæmoglobin under 15 g per 100 ml
3 A cord-blood bilirubin over 2 8 mg per 100 ml
4 A capillary-blood bilirubin of 20 mg per 100 ml or over at any time

Transfusions were also given to babies with ABO hæmolytic disease or with "physiological" jaundice in whom the bilirubin rose to 20 mg per 100 ml or above at any time In a really small baby I would have performed an exchange transfusion at a lower level of bilirubin than 20 mg, but such a case did not arise From November, 1955, to December, 1957, 30 babies were assessed and 15 were selected for treatment

Blood has been obtained from a panel of donors living in the town and has been collected by gravity into silicone-coated bottles, to which 1500 I U (1 5 ml) of heparin had just been added Care was necessary to ensure thorough mixing of the blood and heparin during withdrawal

An exchange of 80 ml per pound body-weight was considered desirable, and enough blood was taken for this 1500 I U of heparin sufficed for 450–600 ml With a large baby more than one donor has been used

While the blood was being collected, preparations were being made for the transfusion, so that the exchange could start as soon as compatibility of the blood had been established Thus the blood was in use within forty-five minutes of collection and while it was still warm

The technique of the exchange was conventional except that a three-way direct-flow syringe (Allen and Hanburys, catalogue no 16486) was used This syringe, together with an infant's (size 8 French) clear plastic œsophageal feeding-tube, greatly facilitates the procedure Before the replacement was begun, the syringe and tubes were flushed with physiological saline solution containing 100 units of heparin per ml This solution was all expelled, and no heparin was injected into the baby apart from that in the donor blood Aliquots of 10 ml were used in all exchanges, in the early cases, at the start of the replacement, 15 ml was removed and 10 ml given until there was a deficit of 25 ml Latterly this precaution has been omitted

At the end of the transfusion the catheter was removed and two or three fine nylon sutures used to close the skin over the umbilical root so that it might be kept fresh and clean in case another exchange was needed Repeat exchanges have been done with the same technique Neither antibiotics nor protamine sulphate were used

Results

In the 21 exchange transfusions with heparinised blood no difficulties arose In two cases, a few drops of blood oozed from the umbilical stump, but this ceased within an hour or two Surprisingly, there was no bleeding at the incision in the case where the saphenous vein was used

The babies stood the procedure very well and nothing resembling the shock syndrome was observed in this series

Discussion

This small series affords no proof that the absence of shock was related to the substitution of heparin for citrate, but the change was made in the hope of avoiding collapse, and this hope was realised From the work of Firt and Hejhal (1957) it certainly seems that citrated blood might precipitate cardiac failure both by direct action on the myocardium and by vasoconstriction in the pulmonary vascular bed In their experiments citrate intoxication caused a rise in venous pressure, and it is well known that such a rise may occur during exchange transfusion

Final hæmoglobin levels when heparinised blood was used were not compared with those when citrated blood was used, but it is a reasonable assumption that the final levels would be higher when the fluid transfused contained only 1 5 ml of anticoagulant solution than when it contained a much larger volume

Because it keeps poorly, and because it would be inappropriate for many patients with hæmorrhage, heparinised blood cannot be used routinely for transfusion But in exchange transfusion for hæmolytic disease of the newborn, time can nearly always be taken to obtain a donor and to match the bloods Time taken to ensure that the blood used for exchange transfusion is fresh and heparinised may be time well spent

This also is the experience of Pew (1956) in his preliminary report of a very similar technique

Summary and Conclusion

In 21 exchange transfusions in newborn babies, the use of heparin as the anticoagulant proved simple and safe Because citrate is toxic in large rapid transfusions, heparinised blood seems preferable for this purpose

SEROUS OTITIS AS A CAUSE OF CATARRHAL DEAFNESS IN CHILDHOOD

DAVID STEVENS
M B Lond , F R C S E , D L O
CONSULTANT E N T SURGEON, BATH CLINICAL AREA

CATARRHAL deafness in childhood is important and often misdiagnosed The schoolteacher may call the child backward, the parent may say that it is inattentive and naughty, and often the child does not realise that it is deaf Catarrhal deafness is not necessarily associated with earache or discharge from the ears, and it is not a very severe form of deafness in most cases Usually it has a variable course, and most children are cured either spontaneously or by the removal of adenoids and nasal infection, but in a few it becomes irreversible, persisting into adult life as a handicap which does not respond to treatment

In the present investigation 96 of 1000 children consecutively referred to an ear, nose, and throat clinic in the past three years had catarrhal deafness All the children with a perforated tympanum, whether wet or dry, were excluded from this number, and so were all the children whose deafness disappeared after politzerisation The children with catarrhal deafness were aged 4–15 years, and there were 50 boys to 46 girls

TABLE I—OPERATIONS IN RELATION TO MIDDLE-EAR FINDINGS

Total	—	—	43

Operative Findings

It is unusual to see a deaf child with a normal tympanum It was therefore decided, at operation, to attend to the tonsils and adenoids and nasal infection in accordance with the history and clinical findings and simultaneously to examine the ears for abnormal appearance or mobility of the tympanum 53 children had fluid in one or both ears, and of the remaining 43 children 31 had empty middle ears on stab puncture, and in 12 stab puncture was not done, because the drumhead appeared normal In 33 of the 53 cases of proved serious otitis the fluid was thin, and in 20 it was very tenacious thick mucus 29 children had previously been rid of their adenoids, and 15 of these still had adenoids Table I sets out the operations in relation to the findings in the middle ear

Duration and Type of Deafness

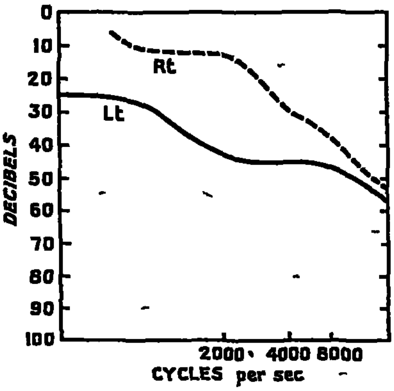
The history of these children is interesting in relation to these operative findings In 31 cases a parent could state the duration of the deafness accurately (table II)

TABLE II—DURATION OF DEAFNESS IN RELATION TO MIDDLE-EAR FINDINGS

—	Fluid present		Dry on stab puncture	No stab puncture
	Thin	Thick		
Duration of deafness (mos)	24 36 12 18 4 10 7 48 12 2 18 1 24 1 2	12 84 24 24 60 12 24 24 12 24	2 3 6	3 2 6
No of cases (% of each group total)	15 (*46%*)	10 (*50%*)	3 (*10%*)	3 (*25%*)

In 15 cases the parents were unaware of deafness at the clinic, and in the remaining 50 cases the parents usually said that deafness came on with colds 3 children were deaf after a previous adenoidectomy, 26 had a history of discharge from the ear, and 16 were said never to have had earache It is surely very significant that the parents who noticed deafness continuously and for the longest duration in most cases were those whose children had serous otitis

Audiographs were recorded in 10 of the more reliable children, and in 6 of these a loss of high tones was found



The accompanying air-conduction graph is from one of these In all the children variation in the degree of deafness was prominent

The degree of deafness was in no case severe, and in 2 children who had fluid in the middle ear only a slightly reduced response to the whispered voice was found Unless, therefore, the ear is examined very thoroughly for abnormal appearance and mobility, such cases may be easily missed

Association with Allergy

In this group of 96 children 8 were considered, by virtue of their history and examination, to be allergic Asthma, frequent sneezing, and bronchitis in infancy were regarded as important in this respect Nasal smears were not done as a routine, but in 2 cases small biopsy specimens from the inferior turbinate confirmed allergy 6 of these children had fluid on stab puncture and in 2 of these it was very thick mucus At follow-up all the children had normal hearing and a normal appearance of the tympanum, although 2 children required a second stab puncture In 3 cases the antra, when washed out, were found to be infected

Appearance of the Tympanum

No specific appearance of the drum characterised serous otitis, but its pathological condition was recognised more and more successfully with practice The mobility of the drum, determined with a Siegle's speculum, was reduced or absent in many cases, but in a few children with very thick mucus the mobility was apparently normal The commonest finding in serious otitis was a fatty yellow colouration of the tympanum, which had its normal lustre and in some cases appeared to be indrawn A slate-grey tympanum was not found in this series 3 children came to the clinic with air-bubbles in the middle ear A fluid level was never seen In 6 cases the drumhead appeared to be overmobile, and in all of these fluid was found at operation

Treatment

Most authorities agree that paracentesis of the drum should be done if fluid in the middle ear is suspected (Politzer 1869, Suehs 1952, Rawlins 1954) It is preferable to do this after inflating the middle ear to prevent damage to the mucosa over the promontory This is not always possible, because in some cases the eustachian tubes are blocked In this series a paracentesis or stab puncture was done under anæsthesia with a Trautmann's myringotomy knife in all the cases in which there was any alteration of the appearance or the mobility of the tympanum In 2 cases the tympanum was of normal appearance and mobility but previous audiographs had shown moderately severe deafness, and for this reason alone a stab puncture was done, thick mucus was found After the stab puncture characteristically a drop of straw-coloured fluid would appear Suction was applied until the middle ear was empty, after which the ear and tube were inflated with the Siegle's speculum When thick mucus was present, suction applied to the stab wound produced a tenacious thread of mucus which could often be drawn out beyond the external meatus When all the mucus was removed, the drumhead appeared baggy and overmobile, and in some children this appearance persisted In a few cases in which no fluid was produced stab puncture restored the mobility of the drum to normal after inflation with the Siegle's speculum

Several children, not in this series, have tolerated a stab puncture in the clinic, but it is important to be quite sure that fluid is present before doing this, because only then is it almost painless Some workers have suggested that two stabs be made at the same time in different parts of the tympanum This seemed to be unnecessary under anæsthesia because then suction could be used, but in adults it is useful in difficult cases No adverse effects resulted from stab puncture The wound heals in a few hours, and the scar migrates to the periphery of the tympanum, where it disappears

Results of Treatment

65 children were examined after an interval of 6–36 months after the operation 9 were still deaf Table III shows the distribution of cases

The presence of fluid in 6 of the 9 cases still deaf at follow-up was confirmed at a second operation

Character of the Fluid

The thin fluid of serous otitis is yellowish, sticky, and mucinous The thick fluid is greyish white and can be drawn out into knotty strands In 2 cases of serous otitis (not in this series) fluid was collected in sufficient quantity to be analysed I am indebted to Dr H J Gibson for the following reports

(1) Bright amber fluid, fairly clear, viscosity ++ Cells 420 per c mm, mainly degenerate tissue cells with a few lymphocytes Protein 8 5 g per 100 ml Sodium 280 mg per 100 ml = 125 m Eq per litre Potassium 33 mg per 100 ml = 8 25 m Eq per litre Film no bacteria found, the mucinous material is stained by mucin-specific stains Culture no growth Conclusion the material consists of a mucinous high-protein fluid probably derived from breakdown of tissue cells, together with plasma transudate

(2) Pale-yellow fluid, small deposit of blood, otherwise clear Red blood-cells ++ No pus, tissue cells, or crystals Film no

TABLE III—RESULTS

—	Fluid in one or both ears at operation	Dry on stab puncture	No stab puncture	Total
Children reporting for follow-up	40	16	9	65
No still deaf	4	4	1	9
Interval since operation (mos)	18 12 34 34 Fluid still present in all 4 cases	13 28 24 12 Fluid now present in 2 cases	24	
Children not attending for follow-up	5	4	3	12
Children operated on in last 6 mos to Dec, 1947	13	3	3	19
Total	—	—	—	96

bacteria Culture no growth Protein 5 2 g per 100 ml Viscosity low A protein electrophoresis showed Albumin 54%, Globulin α1 9%, α2 10%, β 10%, and γ 17% "The protein pattern is similar to the normal serum pattern This would agree with the fluid being a serous exudate"

For comparison straw-coloured fluid from a blocked maxillary sinus was examined and reported on as follows

Yellow fluid, no obvious mucus, fibrin clot + No cells Protein 2 95 g per 100 ml Electrolytes sodium 138 5 mEq per litre = 315 mg per 100 ml, potassium 4 0 mEq per litre = 16 mg per 100 ml, chloride 104 mEq per litre = 610 mg per 100 ml This fluid has the composition of a plasma filtrate

Discussion

The importance of this interesting, elusive, and curable condition lies in the fact that it is not fully looked for in this country as a common cause of catarrhal deafness Serous otitis has many pseudonyms secretory otitis media, hydrotympanum, tubotympanic catarrh, secretory middle-ear disease, &c —indeed "serous otitis" is not a universally accepted name for this condition It was described by Politzer (1869) and Hinton (1874) Between the two world wars little was written about it, and Suehs (1952) could find only 1 case published (in 1927) in America in 1923–40

Ætiology

The cause of serous otitis is primarily a mucus block of the eustachian tube, which mucus, because it is moved down towards the orifice by ciliary action, causes a lowering of pressure in the middle ear with consequent outpouring of fluid The pathology of the fluid seems to confirm this The cause may be

(1) Fixation of the wall of the tube or blockage to its orifice by a growth

(2) Interference with tubal function by malocclusion of the teeth (Bierman and Brickman 1946)

(3) Any condition which delays the mucus lining the tube from emptying by ciliary activity into the nasopharynx—e g

(*a*) *Adenoids*—It should be remembered here what Aschan (1954) says about lymphatic tissue in the tube

> "In agreement with Eggston and Wolff it has been impossible to find any histological evidence, either from fœtal or post-fœtal material, to indicate that the lymphatic tissue of the nasopharynx ever extends as far as, still less invades, the pharyngeal orifice of the eustachian tube"

(*b*) *Nasal infection or irritation*

(*c*) *Air travel.*

(4) Otitis media, often of low virulence, treated improperly with antibiotics This may be responsible for the apparently increased incidence of serous otitis in the past few years

(5) Bullous influenzal otitis

Treatment

Treatment should aim primarily at restoring tubal patency and the normal elasticity of the tympanum by removing the fluid, and secondarily at eliminating associated causes This is not a generally accepted procedure in this country, for Bateman (1957) says about serous otitis "Once again I emphasise that myringotomy is not an essential part of the treatment of these patients"

In this series of 96 children 53 had serous otitis (Of 192 ears 78 were affected, some cases, of course, being unilateral) Of the 53 children affected 20 had thick mucus in one or both ears, and it is in this type of case that spontaneous cure is very hard to imagine One patient under my care, an adult, aged 45, had been deaf for fifteen years and had a large collection of very tenacious mucus in both ears When this was removed, his hearing vastly improved, but it is not quite normal now because of the overmobility of drumheads which has resulted from the disease

Hantman (1952) states "It, i e serous otitis, must be assiduously searched for in children, for here is a golden opportunity for reversing pathology before changes render the process irreversible with permanent hearing damage"

I am grateful to Dr C D L Lycett, medical officer of health for Wiltshire, and to his staff for their cooperation and interest, Mr E Glatz and Mr R D Owen for their generous help and advice, and Miss M Stock for her skilled assistance

New Inventions

A NEW NEBULISER

This nebuliser has been developed over a period of seven years in the Pneumoconiosis Research Unit of the Medical Research Council, in response to a demand for a nebuliser which was robust and easy to clean The new nebuliser not only satisfies these requirements but has a performance at least as good as that of any other similar device at present available

DEFECTS OF EXISTING NEBULISERS

When this work was begun (1951) two kinds of nebuliser were in use in the wards of the Pneumoconiosis Research Unit the 'Collison Inhaler' and various types employing a glass spray unit

The Collinson inhaler is in many respects excellent, but it has one serious defect the liquid is fed into the spray through three blind holes in an ebonite spray unit Since most liquids used in nebulisers tend to form a deposit, these holes inevitably become blocked sooner or later and are then, because they are blind, difficult to clean

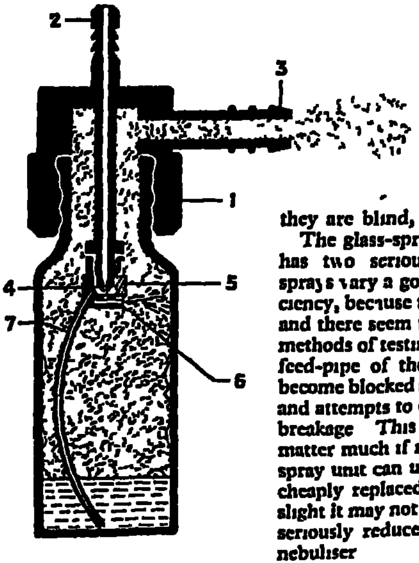

Fig 1

The glass-spray type of nebuliser has two serious defects (1) the sprays vary a good deal in their efficiency, because they are hand-made, and there seem to be no satisfactory methods of testing them, and (2) the feed-pipe of the spray is liable to become blocked after a period of use, and attempts to clear it often lead to breakage This breakage does not matter much if it is obvious, for the spray unit can usually be easily and cheaply replaced, but if damage is slight it may not be noticed, yet may seriously reduce the output of the nebuliser

Other nebulisers have since become available which to a greater or less extent overcome these defects, but only at the cost of complexity, difficulty of manufacture, and the use in some cases of metals In our experience neither chromium-plating nor the use of stainless steel or monel metal prevents corrosion, in any case many pharmaceutical manufacturers specify the use of a non-metallic spray for their products

CONSTRUCTION OF NEW NEBULISER

The nebuliser (figs 1 and 2) is made entirely of 'Perspex', which seems comparable to glass in its resistance to corrosion and freedom from ill effects on nebulised solutions, yet is at least as easy as metal to machine and fabricate in a reproducible fashion

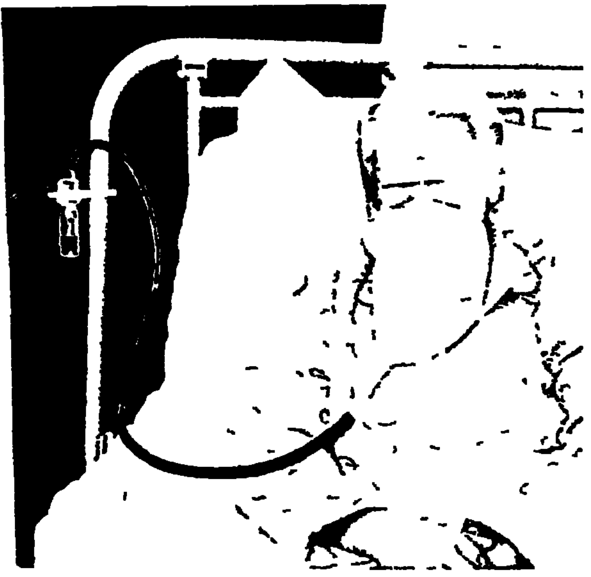

Fig 2.

The nebuliser consists of a solid cap (fig 1, 1) into which can be screwed any suitable bottle—of glass, perspex, polyethylene, or nylon

The thread is that of a glass ' Universal ' container, which is suitable, cheap, and easily obtained Universal containers are very robust, but unfortunately coloured ones are not available at present

The cap carries on its top surface the inlet connection (fig 1, 2) and on one side the outlet connection (3) The inlet connection communicates with a fine jet (4) on to which is screwed a knurled nozzle (5) This nozzle carries a circular baffle plate (6) mounted on an eccentric pillar through which passes a flexible (polyethylene or polyvinylchloride) feed-tube (7) of suitable length to reach nearly to the bottom of the bottle The nozzle has a central opening, the " throat ", which is of such a size that as the air-jet passes through it a vacuum is created which draws liquid up the feed-pipe so that it is atomised by the air-jet. The resulting spray impacts against the baffle plate and the coarser droplets (more than about 8 μ diameter) are trapped, coalesce, and fall back into the liquid

In earlier models the baffle plate was in the form of an anvil fixed in the bottom of the bottle, with its surface about 2 cm away from the nozzle, copying the basic Collison design, but recently it has been found that bringing the baffle to within about 1 mm of the nozzle considerably increases the density of the cloud A small increase in the maximum droplet size results (from 6 to 8 μ diameter) but this does not appear to be any disadvantage in practice.

The nebuliser requires a gas pressure of at least 10 lb per sq in and preferably 20 It was originally designed for a standard oxygen-cylinder reducing valve, which is set at 20–25 lb per sq in , but it can also be used, with a suitable control valve and hose, on the 60 lb per sq in piped oxygen supply that is now installed in many hospitals When connected in this way the nebuliser can conveniently be clipped to the bed with the double clip provided, as shown in fig 2

At a pressure of 20 lb per sq in the standard instrument delivers 10 litres of oxygen a minute, and nebulises about 20 ml of liquid per hour The nebuliser is not suitable for operation with a hand bulb, but can be operated off an electric pump of sufficient power

A blockage can easily be cleared by unscrewing the nozzle (5) with the fingers The blockage is usually in the annular orifice between the jet and the throat, so that once the nozzle is unscrewed it can be simply washed out

Any blockage of the feed-pipe (7) can be cleared if necessary by passing a piece of wire right through it, as it is now open at both ends, but blowing through it is usually sufficient

The jet hardly ever becomes blocked, but if it does, it can be pricked with a fine wire and cleared by blowing back up it

In addition to being practically unbreakable and easy to clean, the nebuliser appears to have as good a performance as any other on the market This has been achieved by comparing it with various other models as they became available, and copying those features which seemed to improve the performance The question of what in fact constitutes a " good " performance is at present a very open one Briefly the criterion used has been the output of droplets in the size range 1–6 μ diameter at a given gas-flow The method of determining this, and its justification, will be discussed in a later publication

In addition to its use for producing therapeutic aerosols, the nebuliser can be used as a humidifier With water in the bottle, and cylinder oxygen, which is practically dry, it produces more than 100% humidification This compares favourably with the usual bubbler devices which, unless heated, never raise the humidity above 50% The disadvantage of using the nebuliser as a humidifier with the usual methods of administration of oxygen is that the relatively high pressure upsets the calibration of the flow-meter supplied for use with the low-pressure bubbler type humidifier This can, however, be rectified by the use of an appropriate correction table, obtainable from the makers

I am grateful to Dr J C Gilson and the staff of the Pneumoconiosis Research Unit for their constant help and encouragement, and especially to Mr V Gubb who made many models of the nebuliser The drawing was prepared by Mr W H Roberts, and the photograph was supplied by Messrs Richard Daleman of 325, Latimer Road, London, W 10, who are the makers

Reviews of Books

Neuropathology

J G GREENFIELD, M.D , F R.C P , consulting pathologist, National Hospital for Nervous Diseases, London, W BLACKWOOD, M B , F R C S.E , M.R C.P E , pathologist, National Hospital for Nervous Diseases, London, W H MCMENEMEY, D M , F R C P , pathologist, Maida Vale Hospital for Nervous Diseases, London, A MEYER, M D , emeritus professor of neuropathology (Institute of Psychiatry), University of London, R M NORMAN, M.D , M R C.P , neuropathologist, Burden Mental Research Department, Frenchay Hospital, Bristol London Edward Arnold 1958 Pp 640 105s

WE have long been waiting for a substantial yet accessible textbook in the English language, in which the accumulated knowledge of the histopathology of the nervous system is integrated and presented critically No-one was better qualified to undertake such a work than the late Dr J G Greenfield, and he and his colleagues have produced a book which promises to remain the standard work of reference for many years to come

All aspects of the pathology of nervous and mental diseases are included, with the exception of tumours Dr Greenfield has provided most of the chapters, and particularly valuable is his introductory account of the normal and abnormal cytology of the neurone and neuroglia, and the sections on infections, trauma, demyelinations, system degenerations of the brain-stem, cerebellum, and spinal cord, and peripheral neuropathies, in which he has distilled the essence of his profound experience He has been helped by several contributors, each one eminent in his own subject Professor Blackwood on vascular diseases, Dr McMenemey on dementias, Professor Meyer on anoxias, intoxications, epilepsy, and psychoses, and Dr Norman on prenatal malformations, birth injuries, and diseases of early life

A historical appraisal of Alzheimer's disease and accounts of the effects of atomic explosions and ultrasound waves illustrate the book's range, and neurological topics in the forefront of present-day interest, such as hypertensive cerebral disease, the blood-brain barrier, carcinomatous neuropathy, temporal-lobe epilepsy, the anatomical basis of prefrontal leucotomy, and the nosological problems of diffuse cerebral sclerosis, are authoritatively discussed within the general framework The lesser-known ways of neuropathology are also explored, and the practising neuropathologist in particular will welcome the detailed account of the primary dementias, and Dr Norman's clear and beautifully illustrated survey of a subject in which the disciplines of classical histopathology still promise rich rewards

This handsome book contains over 500 illustrations of high quality Each chapter has its own bibliography, and there are some 2500 references in all The authors' hope that their labours will give the neurologist and psychiatrist that basis for diagnosis and logical treatment which only pathology can supply is fully realised Not only the pathologist but the neurologist, the neurosurgeon, and everyone working in the neurological sciences will find the book an indispensable source of knowledge To Greenfield, who did not live to see its publication, it stands as a memorial worthy of a life rich in achievements

Principles of General Surgical Management

H A F DUDLEY, F R C S E , lecturer in surgery, University of Edinburgh Edinburgh and London E & S Livingstone 1958 *Pp 203 27s 6d*

IN this newcomer to the important range of books on what is sometimes inappropriately called "minor" surgery, Mr Dudley has used the term surgical management in the title, and this fails to do justice to the contents since many of the methods he describes would be required in medical wards Moreover, the book is concerned with more than principles, it is in fact one to which a student or a newly qualified man could confidently turn for exact direction in such procedures as lumbar puncture, the application of plaster-of-paris, venepuncture, catheterisation, and so on Clear directions and information are also given on more general topics, including nutrition, shock, and electrolyte therapy, and in this respect it is good to record that the book is up to date (corticoid therapy and the effects it may have when surgery is undertaken have been included) The book ends with a chapter on side-room and investigative work, which is a useful collection of the methods required for the common investigations of urine, blood, and other biological fluids One criticism this is a book to be tucked away in a convenient place for ready and rapid reference, but its shape is such that a shelf is required—or a poacher's pocket It is not long, and more convenient proportions may be possible in a later edition

The Biologic Basis of Cancer Management

FREDDY HOMBURGER, M.D , research professor of medicine, *Tufts University School of Medicine, Medford, Massachusetts* London Cassell 1958 Pp 354 75s

IN forewords to this book Dr L V Ackerman, Dr C C Little, and Dr A Ochsner emphasise the need to bridge the often very wide gulf between experimental cancer research and its clinical applications They believe that the book will do this and so broaden the knowledge and outlook of specialised research-workers and also help all doctors interested in cancer and concerned in its treatment

With some reservations, this claim is justified The book's principal advantage over collections of specialised essays lies in its more connected plan, the experimental and clinical aspects are usually developed in successive chapters and then an attempt is made to correlate them whenever possible The drawback, of course, is that no one author is likely to be uniformly successful in covering such an enormous range and he cannot hope to satisfy every specialist worker Even if he avoids factual errors (and there are not very many in this book), a successful balance of emphasis can be achieved only by a critical selection of the data, and that calls for an outstanding grasp of the whole subject Understandably, Dr Homburger has not wholly succeeded in reaching this high standard, indeed he mentions that the idea of this book was rejected by one publisher, who was advised that no one person could write it Consequently, it is to some extent a "review of reviews," fortified by judicious selection, sensible comments, and sound and detached judgment, without pretension to any particular originality

One of its most valuable features is a series of tables summarising the main points detailed in the text Such tables cover, for instance, environmental carcinogenic agents and corresponding cancer sites, details of some of the principal carcinogens, lists of tumours in which chromosomal influences are prominent, neoplasms of endocrine organs, changes in the tumour-bearing host, and a long summary of the natural history and clinical course of a wide range of human cancers

The book is in four parts ætiology, biological properties, diagnosis, and treatment Ætiology is taken to include all causative factors such as the hereditary background, environment, and the influence of viruses and hormones Chemical carcinogens are adequately reviewed, but on p 32 the footnote should refer to benzpyrene and not benzanthracene The device of working backwards—for instance, from Andervont (1942) to the discovery of hepatocarcinogens (Yoshida, 1931)—is used at various points and is rather irritating, and so is the way that the references (generally very good) to each chapter are congregated at the end of the book, without any chapter numbers on the page-headings, either in the text itself or in the reference pages at the end Treatment (including prevention, surgery, and radiotherapy) receives only 28 pages, among which chemotherapy, generally considered to be a promising prospect as well as one of great theoretical interest, gets only 12 pages

Nevertheless, the book as a whole is good and will probably achieve its aim

Principles of Ophthalmoscopy

JOHN K ERBAUGH, M D Norristown State Hospital, Norristown, Pennsylvania Springfield, Ill , Charles C Thomas Oxford Blackwell Scientific Publications 1958 Pp 69 42s

THE details of pathological change in the retina—vascular sclerosis, microaneurysm formation, increased exudation, and frank hæmorrhages—are probably of greater value in identifying the responsible systemic disease than are the pathognomonic pictures of established retinopathy seen in the later stages, and the value of this small book of four chapters rests chiefly on the emphasis it lays on these points Preliminary detection of opacities of the media with the ophthalmoscope is helpfully described, and the details of the normal fundus are considered at length, before the changes seen in the pathological disc, vessels, and fundus generally are reviewed

The general form of the book is attractive, but it seems a pity that more of the excellent colour photographs were not included in place of the coloured diagrams, useful though these are

A Study of the Major Psychoses in an English County

Maudsley Monographs, no 3 MICHAEL SHEPHERD, D M , D P M , senior lecturer, Institute of Psychiatry London Institute of Psychiatry and *Chapman & Hall 1957 Pp 159 25s*

THE applications of statistical methods in psychological medicine have been mainly concerned with assessing improvement under different kinds of treatment, and little attention has been paid to the vital statistics of mental disease

Dr Shepherd here compares the admissions to a county mental hospital for the two triennia 1931–33 and 1945–47 The study is based on examination of the administrative and clinical records of 1223 patients followed for five years after their admission The results show a striking difference in the number and type of admissions during the two periods, and an improved outlook, assessed in various ways, for patients entering hospital during the second period Only the most tentative conclusions can be drawn about the factors that may have contributed to this change

The book shows the drawbacks and limitations of this type of retrospective investigation, and draws attention to the importance of carrying out a well-planned and long-term prospective study of a similar kind Dr Shepherd presents his material well and succeeds in making his mass of figures easy both to understand and to read

THE LANCET

LONDON 5 JULY 1958

The Partnership

“ My job ”, said the Minister of Health ten years ago, “ is to give you all the facilities, resources, apparatus and help I can, and then to leave you alone as professional men and women to use your skill and judgment without hindrance Let us try to develop that partnership from now on ” Since July 5, 1948, the partnership of which he spoke has been strained sometimes to breaking-point, but its development is still perhaps the chief need of the National Health Service For the N H S is something quite different from the conventional State medical service in which the doctor takes orders from Authority it is simply a legislative device by which doctors can continue their work without charging fees and by which the nation's insufficient medical resources can be used to better advantage In organisation and planning to these ends, the most valuable initiative and ideas will often (though not always) come from the people who actually look after patients, but, on the other hand, planning and organisation may weaken professional responsibility and professional enthusiasm unless these people feel that they can have an effective part in it whenever they choose Though they will do all they can for their own patients, they may take no interest in the service as a whole, and in its evolution, unless it specifically offers them participation and hence a chance of getting the results they want To have a sense of partnership in it they must know that their voice will be heard, and heeded, by an administrator who shares the Ministerial concept of his job

For our part we think the National Health Service one of the biggest improvements in the life of this country since the war Thanks to very hard and intelligent work by a great many people, professional and lay, it has done much to better the conditions of medical care, especially in hospital, and it has been an immense comfort to the public But, after only ten years' experience, any jubilation must be at best provisional, for the initial gains to be expected from more rational organisation would be bought too dearly if the cost were an eventual decline in the spirits of the people whose work is organised Even today, unfortunately, the morale of many who take part in the service is not as high as it ought to be in its new bottles some of the wine that should be sparkling has gone flat or even sour Where there is evidence of such depression or disappointment, especially among the young, it should be taken very seriously indeed One of the reasons for it is obvious, and needs only passing mention here because it has become the subject of a Royal Commission Mr Bevan, in his message of ten years ago, said that when fees were abolished the new situation must not mean “ any unfair worsening of a doctor's material livelihood ” This, he said, was vital, and he was right yet the worsening has taken place, and virtually all of us would describe it as unfair Indeed, most of us think that the Treasury has taken advantage of inflation to reduce remuneration in the service—as compared with remuneration outside it—to levels more convenient than those that had been negotiated, and we think that successive Governments have been less than straightforward in their treatment of those who entered a national service at the nation's request This, however, is not the cause of the vaguer but deeper malaise which found expression in a letter we reproduced from the Widdicombe File a month ago[1] The complaint of that letter was essentially that the status of the doctor, as partner in the service, is depreciating and this, we fear, is true We have never been among those who held that hospitals, for example, belong to the medical staff, who can do what they like with them, but we suspect that the pendulum has now swung too far towards lay management of medical affairs, and that consequently the service stands to lose much that doctors ought to be giving it—and which in fact nobody else can give

Though lay intention cannot be wholly excluded, the main reason why most doctors now feel “ out of it ” is the elaboration of administrative machinery Of course, the N H S is a very big, as well as a very complex, organisation, and big organisations always tend to induce bureaucracy—whether the environment is that of Melbourne or Moscow, Manchester or Milwaukee Nevertheless, the British are said to be very good at streamlined organisation when they really give their mind to it So let us examine, if briefly, some of the means suggested for making the administration of the N H S more appropriate to its purpose, and more efficient

THE MINISTRY

The first suggestion, often made in the '40s and lately revived, is that the service should be run by an autonomous national corporation, comparable to the B B C Unhappily, though attractive to the professions, this is constitutionally impossible a body which spends hundreds of millions of public money, which it does not itself raise, must be controlled by a Minister answerable to Parliament On the other hand, there is no constitutional reason why the Minister who looks after the health service need have a department so unimaginatively similar to other Government departments as it is at present Twelve years ago, when the service was entrusted to the Minister of Health and Local Government, the disadvantages were offset by the fact that this was a relatively important department, whose chief had an influential position in the Cabinet, but, when Local Government was removed from it and the residual Ministry was confined to medical affairs, the opportunity might have been taken to redesign it on less conventional lines—recognising that it is the administrative nucleus of an entirely novel kind of public service Even now such reconstruction ought to be considered, and we do not think we are offering a merely medical view when we say that the Ministry would be better suited to its unusual functions, as well as being more acceptable as the head office of the service, if its professional element were strengthened. Repeatedly we have hoped for a Minister who would show himself as the perpetual champion of the service, but, though many Ministers have fought its battles against the Treasury, their duty in public is, on the contrary, to represent the Government—to explain (as a rule) why things cannot be done. Besides, regarded as representative of the service, the Minister has the demerit of continually moving on. Nor can we expect the secretary of the Ministry, though permanent, to assume the role of either titular head or chief officer of a medical service. Is it then really impossible that in this particular Ministry the chief permanent official should be a professional man? Since the subject we are discussing is morale, which depends on people's feelings (rational or irrational), we must say frankly that professional people in the service would regard its control as less remote if it were not so emphatically lay.

---

[1] *Lancet*, June 7, 1958, p 1221

Again, though the Ministry and its servants have done distinguished work in the creation of the service, and have shown both courage and insight in coping with the extraordinary difficulties of its first ten years, their very immersion in its daily affairs hinders their sitting back and forming long views on its development. This was to have been the task of the Central Health Services Council, which in the plans for the N.H.S. was accorded high importance as both a representative and a planning body—being, indeed, described as the brain of the service. But, because of its large size, diverse constitution, and infrequent assembly, the Council has not been found really suitable for this major responsibility, and, though many of its committees have given farseeing advice on particular problems, the Ministry has never used the Council in the way intended, or encouraged it to become a creative force. Planning, in the sense of deciding priorities, has mostly been kept within the Ministry itself, and unquestionably much wisdom has been shown. Many of the achievements of the service owe much to the Ministry's steady pressure—big ones such as the improvement of mental hospitals and the better care of old people, and small ones such as the more frequent visiting of children in hospitals. For general practice it has favoured the practitioner's direct access to pathology and X-ray departments and has promoted the idea of the family doctor as leader of a medical team, and, if its approach to the renaissance of general practice has been more cautious than some of us could wish, we must respect Dr GODBER's explanation (p. 2) that "it would not be right to attempt to formulate a plan for the development of general practice centrally and then impose it." Nevertheless, valuable though this leadership has been, we have never felt sure that the Ministry was facing the underlying issues of the service and had reached a policy for its development as a whole. Do the hospitals, public health, and general practice receive the right share of our resources? If not, what needs to be done to shift responsibilities and burdens and manpower from one to the other? If, for the sake economy and efficiency, contraction of effort is needed at one point, and expansion at another, do the professional and financial incentives in the service promote the desired changes?[2] Rightly or wrongly, we suspect there are still some big lacunæ in the policy of the service and some inconsistencies in its application, and, if the Central Health Services Council is not the right body to study them, the planning capacity of the Ministry might perhaps be strengthened by the appointment of a smaller group—say, half a dozen experienced but not too elderly people, paid a half-time salary, and with access to whatever secretarial and statistical help they want—who would be charged with keeping the policy of the service under continuous review. Nothing much, at any rate, would be lost by trying the experiment, and if such a group were prepared to receive and consider constructive criticism they would also fulfil the incidental but very necessary function of providing an address to which reformers and dissidents could usefully post their suggestions and objections.

BOARDS AND COMMITTEES

Whether or not the machinery of the Ministry needs to be supplemented, there can be no doubt that the machinery of hospital administration needs to be simplified, and an inquiry into it could properly be started soon, before any more interests have time to vest.

Those of us with fairly long memories will recall that hospital regions and hospital groups were both originally conceived for the same general purpose—to get the hospitals of an area to play as a team instead of individually. After much discussion, in which the regions were sometimes to be large and sometimes small, both boards and management committees were put into the service, but possibly this was no more than an example of the extravagant generosity of the times, and we might get on just as well or better without one or the other? From time to time, abolition of the regional boards has been proposed, but, if one is to go, we should ourselves be inclined to eliminate the management committees. Regional boards have acquired, for better or worse, more administrative functions than, as planning authorities, they were meant to have, and, if the number of these boards was doubled, so that the average size of regions was halved, each should be able to maintain direct contact with all its hospitals individually. Day-to-day management would revert to the house committees, which would thus regain their soul, and those hospitals and institutions that have a genuine need to work in close association could link themselves by less formal and elaborate means than a common administration. In this way one of the three tiers of hospital administration could probably be taken out without endangering the structure, and the amount of time and trouble this would save would be enormous.

Even so, the simplifying process should not stop there, for perhaps as much good, or more, could come of fresh examination of the constitution of the boards and committees themselves. We should not be surprised to find that at least half their work arises from their being too big, for a big board or committee, meeting only occasionally, can seldom reach a decision on any important problem except by referring it to a committee which can go into it more carefully Unfortunately (if we may propound a variant of PARKINSON's law [3]) the amount of work increases with the number of *committees* available for its completion Certainly it has been very helpful to the N H S that so many able people should have been willing to give up so much time to the conduct of its boards and committees, burning gallons of midnight oil over its interminable agenda, and something would as certainly be lost by having smaller boards which would contain less variety of experience. Yet the gain in expedition and labour would be quite immense if (as TAYLOR suggested years ago [4]) the regional boards were reduced to an average of eight members, meeting often enough to be fully familiar with their business and able therefore to take the decisions themselves They would have to be paid an honorarium of course, and a big one: but their job would, after all, be no less important than that of the executive directors of other big concerns, and if the Government want the best people for such work they cannot sensibly limit their choice to the rich or retired.

---

[2] *Ibid* 1956, i, 237

THE UNITED VOICE

How would such streamlining of hospital administration affect the partnership we are advocating? Clearly, it would reduce the likelihood of doctors serving on the executives, and would thereby disappoint those who want to see the professions heavily represented on the boards and committees which administer the service But in our view the demand for this kind of professional representation is and always has been misguided [5] A board ought, naturally, to give more weight to the views of a medical advisory committee, presented unitedly, than to those of its individual medical members, who are (or should be) appointed for their personal qualities and not as experts or as accredited representatives of the hospital staffs But in practice the layman will inevitably be confused if he receives medical advice from two quarters, and the influence of the advisory committee can easily be weakened by the presence of doctors on the board, who may speak with a different voice. Indeed, the result may be that the board, getting divergent guidance, will feel free to take its own line Unless therefore, the professions are granted absolute majorities on the boards (which seems improbable) they will do best to concentrate on providing, for each executive, an advisory committee which is in a position to offer a considered opinion on behalf of the professions concerned. If the chairman of this committee, sitting with the executive as a non-voting member, produces an expert opinion of this kind, his board will think at least twice before ignoring it To go on trying to make the boards themselves representative of everybody and everything will mean that they get bigger rather than smaller, and that they do their work through even more committees The proper course, as we see it, is to reduce the administrative bodies both in number and in size, but to make sure that each of them, in deciding matters of moment, has the benefit of a corporate professional opinion

PROFESSIONAL INITIATIVE

If it were true that our profession had been nationalised (as people so often and so wrongly assert), doctors would be able to influence the service only through these official channels But in point of fact, though most medical men and women work in contract with public bodies, the profession has a separate and thriving independent life, based on its own societies and institutions We cannot too often repeat that in this country doctors are *not* State officers or Civil Servants, and it would be a great pity if, even within the service, they began to feel that initiative must always come from the centre rather than the periphery For example, those who think that general practitioners ought to have part-time hospital appointments need not wait for an administrative circular but should set about seeing whether and how what they want can be arranged in their own areas, for that is how new things are still most often done. A more vigorous suggestion we have heard is that, instead of reflecting negatively on the defects of a tripartite service, local doctors from all branches should form a small unofficial group of their own—to look into what is wrong in their area and to make sure that it is put right. A really active ginger group of this kind might (for intraprofessional reasons) find it convenient to meet anonymously and remotely, hooded and at midnight, but no such anxious considerations need deter those of more academic or timorous habit who prefer to make their criticisms of the service, and their proposals for its amendment, through their associations, colleges or faculties. In the past year many of the principal professional bodies have set out some of their opinions in memoranda of evidence to the Royal Commission on Remuneration, but in general their corporate capacity for constructive thinking on the medical services is too little cultivated The British Medical Association hopes to undertake a review of these services, which should be invaluable if it rivals in foresight the report of the Association's Medical Planning Commission before the war Exceptionally well placed for making background studies of medical policy is the Royal College of Physicians of London which could helpfully produce more of the documents with which it has sometimes stimulated professional discussion In promoting the development of the service, King Edward's Hospital Fund and the Nuffield Provincial Hospitals Trust (whose latest progress report appears this week [6]) have contributed ideas as well as money Of all the King's Fund contributions, none perhaps will do more good in the long run than its Administrative Staff College, where partnership is seen and presented as a necessity On p 42 Dr. W S PARKER suggests that there should also be a general staff college which could give young doctors an administrative understanding that would later help them to help the service Unquestionably medical knowledge, in its growing complexity, will not be fully applied unless quite a lot of members of our profession are led to take a special interest both in what CLARK [7] calls administrative therapy and in the larger subject of therapeutic administration.

[6] A Record of the Progress of Schemes and Descriptions of New Projects 1955-58. Fourth Report. Nuffield Provincial Hospitals Trust Nuffield Lodge Regent's Park, London, N.W.1

Among national organisations, the N H S is remarkable because it represents a new kind of partnership between the State and the professions its purpose is to enable people to work effectively to their own professional standards This partnership breaks down if either side disclaims responsibility—for instance, if a doctor, conscious of some remediable administrative fault which is lowering the quality of his work, does nothing more positive than blame "the service" Such dissociation of the administrative and professional parts of the undertaking always does damage, for discontent without appropriate action is anything but divine Moreover, the truth is that, though administrators have been slow in solving some of the problems of the service, there are others which only the medical profession itself can solve The rigid and routine nature of training for specialties, and the barriers between them, are the result of professional policies—and policies by no means confined to this country Is it the administrators of the N H S who are making it so difficult for young men to have the useful experience of going for two or three years to one of the Commonwealth countries where they are so badly needed? How much of the difficulty of getting into general practice has arisen because practitioners no longer set sufficient store by postgraduate hospital training? Even the problem of the senior registrars and the S H M O S is presumably insoluble—whatever the Government do—until consultants make up their mind about the advantages and disadvantages of a swelling of their ranks, with perhaps a consequent diminution in their prestige Looking round at the many difficulties of the service which obviously demand some fresh approach, it seems that the best means of making progress would be a statutory period of amnesia in which all of us forgot what we had ever said before Meanwhile, however, we make no apology for recalling and repeating the plea for partnership which appeared in our editorial of July 3, 1948

"If we continue to think of the National Health Service as a State service it will fail, but if we recognise it as our own service we can make it a great and increasing success"

The Ætiology of Leukæmia

FOUR years ago we reviewed the work of LUDWIK GROSS on transmissible mouse leukæmia [8] GROSS used for his experiments two contrasted *inbred strains* of mice, the Ak strain, 70% of which develop lymphatic leukæmia at the age of 7–10 months, and the C3H strain in which the incidence of spontaneous leukæmia is only 0 5% Cell-free filtrates were prepared from the organs of leukæmic Ak mice, when these were inoculated into newborn C3H mice, less than 24 hours old, nothing happened immediately and no tumour developed at the site of inoculation, but in the mouse's middle age (the normal life-span is 2½–3 years) 81% of these mice developed leukæmia, if the inoculation was delayed until the mice were 2–6 days old, only 55% became leukæmic, and if the inoculated mice were more than 7 days old, no leukæmia occurred GROSS also showed clearly that whatever was transferred from the leukæmic Ak mice caused leukæmic changes in the C3H cells themselves, since the C3H leukæmia could only rarely be transplanted back into Ak mice GROSS concluded that the lymphatic leukæmia in Ak mice was caused by an agent transmitted through the embryos from one generation to the next, and, since not all mice carrying the agent develop leukæmia, and some may die from other causes after they have transmitted the agent to their offspring, true hereditary transmission may be simulated When GROSS attempted to prove that this leukæmic agent was filtrable, some odd results appeared If the material was filtered through Selas microporous porcelain, quite a lot of the inoculated newborn C3H mice developed parotid tumours at an average age of 3 3 months, instead of leukæmia at about 10 months On the other hand material filtered through Berkefeld N candles produced mostly leukæmia and a few parotid tumours These unexpected findings clouded an otherwise clear story

On the whole these results have been confirmed by others, [9–11] and several new points have emerged [12] The transmissible agent from the Ak mice has been found to induce subcutaneous fibrosarcoma in some animals as well as parotid tumours in others This finding underlines the oncogenic potentialities of the agent But GROSS found that, using a particular inbred strain of mice, only leukæmia was produced by inoculation and tumours did not appear [13] A more surprising experiment showed that cell-free extracts from tissues of apparently *normal* Ak (or similarly leukæmia-prone C58) mice inoculated into newborn C3H mice could induce leukæmia and, in a few instances, parotid tumours [14] Further experience has shown that there is considerable variation in the potency of the leukæmogenic agent and in the susceptibility of the hosts even among inbred strains When this was realised potent agents were selected for study, and it was found that the potency could be increased by cell-free passage through generations of C3H mice GROSS has now developed a leukæmogenic agent that will induce leukæmia in up to 97% of inoculated suckling C3H mice 1–14 days old after a latent period of only 3–4 months

The technique of using newborn mice less than 1 day old for the inoculation of tumour-producing agents has now been adopted by several laboratories, and some curious results have been reported GRAFFI et al [15] prepared filtered extracts from Ehrlich mouse carcinoma and some other tumours, and inoculated them into a strain of mice known to have an incidence of spontaneous leukæmia of less than 1%, 34–75% of the inoculated mice developed myelogenous leukæmia after a latent period of 4–8 months Friend[16] obtained similar results and showed that the myelogenous leukæmia could be transmitted by inoculation of cells into adult mice of the same strain This phenomenon of induction of leukæmia by cell-free extracts from tumours is the reverse of Gross's induction of tumour growth by inoculation of leukæmogenic agents Gross considers that these findings emphasise the importance of variation in the recipient, and points out that parotid tumours develop from leukæmic filtrates only when the inoculated host is less than 16 hours old; above this age, only leukæmia appears

A set of experiments supporting the hypothesis that the leukæmogenic agents are viruses have been reported by Stewart and her co-workers[17] They showed that the leukæmic agents could be grown in tissue-culture on mouse kidney or chicken chorion allantois and would then induce parotid tumours, but not leukæmia There are some other properties that support the virus hypothesis For example, the material can be stored without loss of potency at —70°C for $3^1/_2$ months or so, studies with the ultracentrifuge suggest that the leukæmogenic particles are about 50–70 mμ in diameter, and electron microscopy shows particles of a somewhat similar order Extracts filtered through membranes of 340–200 mμ porosity can induce leukæmia, but extracts filtered through membranes of 140–93 mμ porosity still induce parotid tumours[18]

To explain all these findings Gross[19] proposed the hypothesis of "vertical transmission" of a pathogenic agent By this term he means the transmission of extraneous pathogenic agents from one generation to another by germinal cells or occasionally, as in the mammary carcinoma of mice, through the mother's milk This contrasts with the usual methods of transmission of infectious diseases by contact, by food, through the air, or through the agency of insect or other vectors In these known methods of transmission, the transfer takes place in a few days or weeks, and thus the spread can often be traced without difficulty But "vertical transmission" works differently, and according to Gross has the following characteristics

The pathogenic agent, transmitted by the germinal cells or the mother's milk, may remain latent for a considerable portion of the host's life-span so that the infected animal appears in perfect health but can still transmit the seeds of disease to its offspring, thus C3H newborn mice receiving the pathogenic agent from Ak mice do not develop leukæmia till middle age, and by then they have mated and may have passed on the disease, via the germinal cells, to their own offspring Sometimes the agent may not become activated at all during the lifetime of the host, and in some instances an agent is harmless for its own carrier host but can cause fatal disease when transferred to another strain or species Gross points out that several examples of this type of transmission are known in nature (e g, *pebrine*, the silkworm disease studied by Pasteur, mosaic disease of potatoes; and Rocky Mountain fever and tularæmia transmitted through the eggs of tick vectors) Certain types of bacteriophage are also transmitted from one generation to another, Lwoff[20] showed that bacteriophage may remain dormant until activated by certain agents, including X rays, and once activated the phage may destroy its own host by lysis The activating agents for leukæmia are hardly known, we suspect that ionising radiations and chemical poisons such as benzol may have this effect, but we have no idea how they work or what is the nature of the change induced in the transmitted pathogen

In four years, then, Gross has consolidated the evidence for the "vertical transmission" by cell-free agents of mouse leukæmia and certain mouse tumours, and it is likely that chicken lymphomatosis is similarly transmitted But whether these ideas can be applied to human leukæmia is doubtful Gross himself points out that the evidence will be hard to get. Clearly human leukæmic material cannot justifiably be inoculated into newborn infants Tracing an agent transmitted vertically requires the study of several generations, human leukæmia was recognised as a distinctive disease only a century ago, and its modern study with reasonably accurate case-finding dates back hardly a generation Another difficulty, raised by the fact that tumours as well as leukæmia can be produced by inoculation of material from a single source, is that we do not know whether we are dealing with a single agent with varying potentialities, or several agents transmitted at the same time Four essential conditions seem, on Gross's theory, to be needed for the development of leukæmia[19] (1) inherited susceptibility of the host, (2) the presence from birth of a leukæmogenic agent, (3) an activator that may be intrinsic (metabolic or hormonal) or extrinsic (physical or chemical), and (4) conditioning of the host to allow the activators to stimulate the pathogenic agent to produce leukæmia (or tumour) So far as human leukæmia is concerned, we know hardly anything about these points We have no means of detecting whether a pathogenic agent has been transmitted or is still present in the parents of the leukæmic patient, and all we know of activation is some suggestive evidence that exposure to X rays or other ionising radiation can be followed by leukæmia[21] and that certain chemicals may act in a similar way

Despite the impasse that study of the viral transmission of leukæmia and tumour formation seems to have reached for the moment, this work is clearly of immense interest. But to the physician dealing with the leukæmias, the interest after four more years' research remains academic Indeed, if Gross is right, we are faced with an undetectable leukæmic agent transmitted at birth which becomes active in a set of circumstances at present undefined. Such a theory holds out little hope of therapeutic advance.

Annotations

NEUROLOGICAL COMPLICATIONS OF ASIAN INFLUENZA

In the recent epidemic of Asian influenza the illness was usually neither severe nor lengthy, but in a few of the enormous number of cases complications developed, some of which involved the nervous system These neurological complications are discussed in four contributions that appear on earlier pages of this week's issue Encephalitis is perhaps the best established of them Commonly it arises about the fourth to tenth day after the onset, when the patient seems to be recovering or to have recovered from the initial illness, and it is characterised by impairment of consciousness with bilateral extensor plantar responses and few or no localising signs In the purely encephalitic cases the cerebrospinal fluid (C S F) is normal The electroencephalogram (E E G) is extremely abnormal with pronounced delta activity which may be continuous or occur in bursts on a predominantly flat record The patient's condition may be critical, but recovery is usual and in most cases complete Other types of encephalitis attributed to Asian influenza include encephalomyelitis and an ataxic encephalitis [1] similar to that which may follow chickenpox It may, however, also present as a psychotic outburst in which the patient becomes restless, noisy, and violent In these outbursts the E E G is grossly abnormal with distinct delta activity, justifying the view that they are a symptom of encephalitis and do not represent a latent psychosis which has been revealed by a generalised infection

Observers from Bombay [2] to Birmingham and Barbados to Jerusalem believe that their cases of encephalitis were due to Asian influenza, and many will agree with them, but it is difficult to prove the connection beyond doubt Clinical evidence can be supported by antibody titres indicating that Asian influenza coincided with encephalitis, but Dr Flewett and Dr Hoult (p 11) show that this evidence must be evaluated critically They point out that when the cases arose there was an epidemic of influenza in the neighbourhood, and there was therefore a good probability that any person in the region would show evidence of recent infection, and that this probability was even greater in the hospital population than in the general population Nevertheless, viewing the evidence as a whole, it is reasonable to conclude that the encephalitis is the result of the influenza Whether the encephalitis is due to the presence of the virus in the brain, to activation of some other organism by the influenzal virus, or to the provocation of an allergic reaction is unknown This problem arises in other forms of encephalitis, such as those associated with mumps, chickenpox, and vaccinia

Another complication of Asian influenza is aseptic meningitis, which may be found with or without encephalitis Udani et al [2], describing influenza in children in Bombay, report 5 meningitic, 5 encephalitic, and 11 mixed cases Acute polyneuritis has also been described in association with influenza, and 2 cases are described by Dr Flewett and Dr Hoult which might be attributed to Asian influenza But here the specific relationship is much less clear, and it will probably further confuse the problem of the ætiology of polyneuritis if influenza is regarded as a specific cause

MENTAL HEALTH AND NURSERY-SCHOOLS

In a nursery-school the easy introduction of the 3-year-old to a wider society is an "upward extension of the family rather than a downward extension of the primary school," [1] and sets a pattern for good relationships in the future It is not surprising that those in charge of child-guidance clinics and others who have to care for children with special problems—for example, the partially deaf—wish to secure the admission to nursery-schools of some of the children The character of nursery-schools would, however, be changed if too great a proportion of handicapped children were admitted and they ceased to cater for a cross-section of the community

At a recent conference in London of the Nursery Schools Association, the part that these schools could play in the promotion of mental health was examined against the background of financial restrictions Even in London there are places for less than 10% of the children between 3 and 5 Teachers from nursery-schools described, as did Taylor twenty years ago,[2] the problems of young mothers in suburban communities, as well as the frightening anxieties of the mother beleaguered in her 16th-floor flat while her son plays in the asphalt jungle below It is to the credit of the education committees of London and Bristol that between financial crises they have been able to slip planned nursery-schools into the ground-floors of some of the new blocks of flats We may need nursery-schools as well as colleges of technology in the coming years

PENICILLIN AND CHLORAMPHENICOL

The action of penicillin is primarily bactericidal, whereas that of chloramphenicol is primarily bacteriostatic In a summary of evidence from in-vivo and in-vitro experiments Jawetz and Gunnison [3] showed that the effect of combining two such agents is unpredictable The result depends on the relative amounts of the two antibiotics in the combination and on the organism's sensitivity to the bactericidal drug That antagonism between antibiotics may be a clinical reality hazardous to the patient was shown by Lepper and Dowling,[4] who reported that when penicillin and chlortetracycline were used together in the treatment of pneumococcal meningitis 79% of patients died, whereas only 30% of patients died when penicillin was given alone in the same doses

Many in-vitro studies of the action of penicillin and chloramphenicol in combination against a number of bacteria demonstrated antagonism, especially when the test organism was a gram-positive coccus, but others did not confirm this and some even revealed synergism These conflicting observations probably result from the diversity of in-vitro methods and the variety of test organisms and from the different ways in which the experimental results were interpreted The results of in-vivo experiments are also inconclusive In the therapy of experimental infections in mice, these two agents were antagonistic when treatment was restricted to a single injection of the drugs [5 6], but these single-dose experiments do not reproduce the conditions in which antibiotics are used clinically Speck and Jawetz [7] reported that penicillin and chloramphenicol, administered daily by intraperitoneal injection for five days, were antagonistic in the treatment of a subacute streptococcal infection induced in mice by the intramuscular injection of *Streptococcus pyogenes* But when Ahern et al [6] treated the infection produced in mice by the intraperitoneal injection of *Str pyogenes* with parenteral penicillin and chloramphenicol in doses that maintained adequate blood-levels for two or three days, they observed no interference, the combination afforded the same degree of protection as penicillin alone In a series of articles, Jones and Finland have attempted to evaluate the activity of two antibiotics in combination by determining the antibacterial activity of the plasma of healthy people at intervals after the drugs had been administered separately or together We have referred to some of their earlier work,[8] [9] and now Finland et al [10] have tested phenoxymethyl penicillin and chloramphenicol in this way Chloramphenicol did not interfere with the action of penicillin against three different gram-positive cocci—a group-A streptococcus, a type-2 pneumococcus, and a *Staph aureus*—nor did it add measurably to the activity of the same dose of penicillin given alone They concluded that the combination has probably no clinical significance

Even if there is no untoward interaction between chloramphenicol and penicillin, it is difficult to envisage a legitimate clinical indication for prescribing these two drugs in combination

ANAPHYLAXIS WITHOUT PREVIOUS SENSITISATION

THOSE who have to administer antitoxin are alive to the danger of anaphylactic shock in patients who may have become sensitised by previous treatment with antitoxin Presumably in sensitised persons antibodies have been produced to serum-proteins present in the earlier dose of antitoxin, and the reaction of these antibodies with the protein in the subsequent dose of antitoxin gives rise to some toxic substance—possibly histamine—which may prove lethal unless adrenaline is administered promptly The relation of anaphylaxis to allergy, the explanation of the toxic effect of the combining of antigen and antibody, and the site of the injury reaction are still mysteries But anaphylactic reactions may be elicited in vitro, for smooth muscle such as strips of uterus or intestine from sensitised animals contracts when it is brought into contact with the specific antigen to which the animal is sensitive [11] Not only does anaphylactic shock occur in animals previously sensitised with the antigen, but so-called " passive anaphylaxis " is observed when administration of antibody from another animal is followed after an interval by administration of the specific antigen. It has been suggested that the time interval before maximum sensitivity to passive anaphylaxis develops may represent the time necessary for fixation of antibody to tissue cells [12]

A reasonable view therefore would be that anaphylactic shock is due to the union of antigen with antibody in or at the surface of tissue cells causing cell injury and leading to the production of a histamine-like toxic substance by the cell On the other hand, acute shock in guineapigs can be elicited by injecting a mixture of antigen and antibody which have already been incubated together in vitro for a short time,[13] so it is not necessary for the antibody to be first anchored to the tissue cells before coming into contact with the specific antigen This type of acute or even fatal reaction after injection of " toxified " serum is sometimes regarded as distinguishable from true anaphylaxis and is described as anaphylactoid shock The severe shock in guineapigs produced by injecting soluble complexes of antigen and precipitating antibody [14] is presumably of this type Recently [15] it has been found that injection into mice of soluble antigen-antibody complexes produces severe shock, the antigens used being bovine serum-albumin and *Hæmophilus pertussis* vaccine In some cases the soluble complexes were prepared by adding an eightfold excess of antigen to the appropriate antibody, and in other experiments equivalent amounts of antigen and antibody were first mixed, and the resulting precipitate was washed and then dissolved by adding a tenfold excess of antigen With the preparation from the washed antigen-antibody precipitate the mortality among the injected mice was lower This suggests that the shock-producing factor may be formed when the antigen and antibody combine in vitro and is removed by washing the precipitate It is perhaps significant that peptone shock produced by protein breakdown products closely resembles anaphylactic and anaphylactoid reactions

IN ARDUIS FIDELIS

BY royal warrant of June 23, 1898, the Army Medical Staff was amalgamated with the Medical Staff Corps to form the Royal Army Medical Corps, and on Tuesday of last week the diamond jubilee of the Corps was celebrated with due magnificence at a service in Westminster Abbey attended by Queen Elizabeth the Queen Mother, colonel-in-chief On the following day the British Medical Association, whose persistent pressure on Governments did so much to bring about the R.A M C 's formation, gathered a large and notable audience in its great hall There they had the rare experience of hearing a commemorative oration delivered by an orator—yet in an unassuming way that made it wholly delightful

Sir Gordon Gordon-Taylor had qualified himself for the occasion first by graduating in classics at Aberdeen in the year when the R.A M C was born, and secondly by his surgical service with the Army in France in the first world war—long before the second transformed him into an admiral Having recalled some of the great but faraway figures of British military medicine, he spoke of the R A M C 's contribution to preventive medicine implied by four of the names carved outside the London School of Hygiene—Parkes, Leishman, Bruce, and Ross Then he turned to the men he knew in France, bringing each to life for a moment by his memories "The whole world is a tomb for heroic men ", and he told us how, the week before, he had paid another visit to Flanders, in the rain so characteristic of that country, and had stood beside the grave of Noel Chavasse, in the cemetery at Brandhoek, which lies exactly where Arthur Martin-Leake had the main dressing-station of his field ambulance These two doctors both received the Victoria Cross twice To the present members of the Corps he said that its great traditions are safe in their hands " Fidelity is, next to courage, the loveliest virtue "

Prof ANDRIJA STAMPAR, a former president of the Assembly of the World Health Organisation, died on June 25 at Zagreb

At their meeting last month the Central Health Services Council re-elected Lord COHEN OF BIRKENHEAD as their chairman.

CASE-WORK IN THE TEACHING OF PSYCHIATRY

T T DAVIES
MEDICAL STUDENT

E T L DAVIES
MEDICAL STUDENT

DESMOND O'NEILL
M C, M D Belf, M R C P, D P M
PHYSICIAN

DEPARTMENT OF PSYCHIATRY, ST MARY'S HOSPITAL, LONDON

WRITING about the fragmentation of knowledge, a distinguished physician and teacher of medicine said

> " I sometimes feel when I listen to these eminent scientists that their arguments are all perfectly valid, except that they have forgotten one thing—that the subject of their improving exercises is a living, feeling, and, we hope, thinking human being Nowadays, be it in medicine, be it in education, be it in political reform, there seems to be a tendency to forget the individual "

This observation of Pickering's (1955) about the medical student applies with even more force to the patient the more advanced the physical methods of diagnosis the greater is the risk that the ill person will get lost in a welter of figures and charts and wave-recordings

We describe here an experiment in the handling of ill and emotionally disturbed people by the student himself, under supervision by a senior We believe that case-work of this kind can help in a practical way to prepare him for dealing with the patients he will meet in his professional life We think it better that he should be exposed to this experience within the framework of a teaching hospital than in the rough and tumble of practice without adequate guidance

In the clinical part of his training the student of medicine learns by observing his seniors at work, by reading, by listening to lectures, and by working with sick people The degree of participation, or involvement, in his work is least when he is passively taking information in, and most when he is actively concerned in what is happening to the patient Methods of teaching that encourage participation, such as the case-seminar with discussion, seem to engage the student's interest and enthusiasm more than the purely didactic methods, though in a balanced course both have their place When patients are entrusted to his care, his attitude undergoes an important change he moves over from being an observer of the art of medicine to being a participant, albeit in a subordinate role

In the teaching of psychiatry two kinds of knowledge have to be imparted (1) the syndromes of mental illness, major and minor, and their diagnosis and treatment, and (2) the understanding and management of a personal relationship between the doctor (or the doctor-in-training) and his patient Case-work, as we use it, contributes a great deal to the second, but it does not take the place of systematic teaching in the first

The ability to take a complete and meaningful history of the patient's illness calls for skill in interviewing, a skill which is of first importance in clinical medicine This ability is one function of an effective doctor-patient relationship, it can be fostered through experience and discussion, and continued contact with the patient is here valuable, for it allows the novice to confirm, refute, or amplify his initial impressions Direct questioning of the patient is not always the best approach The student needs also to learn how to listen, when to comment, and when to keep silent, and how to evaluate what the patient says Some patients require help to express their thoughts, and others ramble so much that a little direction has to be applied Knowledge when to do one of these and when the other takes time to acquire The attitude of the interviewer is important in determining the course of the interview, and with repeated interviews the student comes to see how this influence operates

Method

The first step is that the student who wishes to know more about psychiatry comes to the outpatient clinic on the day when new patients are seen This attendance is voluntary, and thus the students who have taken part in the experiment are a self-selected group One, two, or three students (not more) " sit in " on the consultant's interviews with each patient When the nature and the severity of the illness have been assessed by the consultant, and the patient has left the room, the case is discussed, if it seems suitable for handling by a student, one of those present may be asked whether he would like to take the patient on At this point there is a " feeling-judgment " to be made, if the student feels unduly irritated or antagonised by the patient and his complaints, or unduly attracted, it will be prudent to decline In his later career he will, of course, have to deal with patients of this kind, but it is unwise for him to begin his case-work with one of them If he decides to accept, appointments are made for the patient to attend once a week during clinic hours, when the supervisor (the consultant or his deputy) is available

Patients chosen for case-work fall into two broad classes

(1) Those with anxiety states, or depression, or one of the common stress disorders, such as abdominal discontent These can be helped, and often helped considerably, by regular interviews with ventilation of feeling and the working-through of personal problems

(2) Those with an established illness, such as a paranoid state, which is not progressive Patients in this category attend for observation, the student learns by observing them and reporting back to his supervisor As a rule there is little else to be done, except when some environmental change is called for, this will be decided on after a conference with the social worker

Perhaps from a third to a half of the patients coming to a psychiatric clinic can be assigned to a student Where the illness is too massive or too complicated, or where there are special features which make the case unsuitable (e g, homosexuality with much tension), the patient is dealt with in some other way When the student undertakes to look after a patient he must see to it that his sessions in the clinic are kept free from other duties for a reasonable distance ahead—say two or three months

The student is present on the patients' first attendance at the clinic and is introduced to them as a doctor-in-training he is thus recognised as one of the team The patient selected for case-work is asked whether he will agree to the consultant calling on the student for assistance in the handling of his case, and this agreement is always forthcoming, if the selection has been wise The patient knows that he can always ask to see the consultant, or supervisor, again at any time, it is surprising, and instructive, to see how seldom this request is made

Where the patient is having medication—say, with a sedative drug—and makes an inquiry about this at his interview with the student, he is told that the consultant's advice will be sought before any change is made In general, drug therapy is kept to a minimum, or omitted altogether, during the course of case-work

Supervision

Close supervision of the student's work is an essential part of the plan His session with the patient will last 40–50 minutes, he may make notes at the time or write a summary of the conversation afterwards He then brings his notes directly to the supervisor, and the material of the session is discussed at some length If there is a difficulty the patient may be brought back for a fresh appraisal by the supervisor From the student's interview there will emerge (1) the present state of the patient, and how the illness is progressing, (2) further data about the emotional background of the illness, and (3) the reaction of the student to what the patient says and does, this is especially important

During the supervisory sessions the aims of the departmental team in helping the patient are formulated The tendency of the beginner is to strive for perfection, and to feel frustrated if a perfectly harmonious adjustment cannot be achieved Discussion with the supervisor, and with his fellow-students, promotes a realistic assessment of what can and cannot be done

Some direction by the supervisor of the student's activity will, of course, be necessary this does not consist of a series of orders but rather a working-out by student and senior together of the best and most practicable way of handling each new situation as it arises In the main the student's attitude will be neutral and cautious, he takes care to refrain from taking sides or being drawn into giving advice

Termination of the case-work relationship does not seem to offer special difficulty The rapport between the student and his patient is never allowed to become too intense, so that " weaning " is not attended by depression or a recurrence of illness The patient retains his contact with the clinic and hence does not feel cut off and rejected

Attitude of Student

Naturally at the outset the student is diffident—he is feeling his way At this stage he is advised to say as little as possible, his main task is listening, not talking, and he must strive to adopt a sympathetic, attentive, noncritical attitude which will encourage the patient to unburden himself In the opening phase of his work with patients the student commonly feels mildly guilty He feels that he is " only a student ", and wonders if it is fair for the patient to be seen by him and not by a qualified doctor He soon comes to see, however, that the patient generally benefits from their sessions together, and that his own professional status is less important than the qualities of personality he can bring into the situation His feelings of guilt and inadequacy should be brought out into the open as soon as they appear and freely discussed he can be shown readily enough that he is putting into the patient-relationship at least as much as he is getting out of it

Another common reaction is one of discouragement at the slow rate of progress in the illness—e g , a long-standing anxiety depression From this he begins to learn how to tolerate patients who get better slowly, or perhaps do not progress at all, and that the determining causes of improvement, or lack of improvement, are much more in the patient than in him He learns that every illness, and every human relationship, has its ups and downs, and he takes a more objective view of the downs The student is never given a patient with whom he feels entirely out of sympathy, he is free to refuse the case if the patient is much older than himself, or perhaps too close to him in age, or if he feels that he might get entangled in the patient's problems, or for any similar reason

The possibility of entanglement with the patient is sometimes advanced as an objection to case-work, but in practice it is very rare One of us, who has used and tested out this method of teaching over a number of years, has come across no untoward consequences for the patient or the student (O'Neill 1955) Occasionally the student will become overinterested in or overconcerned with his patient, but with regular and close supervision this can easily be dealt with The student's lack of experience of medicine and of life is in our view offset by the fact that he is, apart from examinations, under much less heavy personal pressure than the overworked general practitioner

Case-work should remain a voluntary activity It would be unwise and profitless to make this part of his teaching obligatory. The student who is keen to learn will ask for it, the others should not be compelled, and, if they were, would learn nothing and perhaps become anxious and resistant

Role of Social Worker

The student who is looking after a patient has access to all the services of the department, and can, if need be, call on the psychiatric social worker to see members of the patient's family, or to advise and help with practical social problems Our practice is that the case is thoroughly discussed by the student, the consultant, and the social worker in conference before the referral is made, in this way the role to be taken by each is defined and understood, and there is no overlapping After the social worker's interview she will discuss her findings with the student or in conference It is a valuable experience for the student to join in a team with workers in other disciplines, he can observe the social worker's approach and learn from her about the importance of family setting, housing conditions, problems of adaptation to a new culture, and the other determinants of illness which are her special province

Objections and Advantages

Some of the risks and objections have been dealt with above One theoretical objection is that the kind of student who is attracted to case-work in psychiatry is likely to be a " neurotic " person seeking therapy for himself On the contrary, the students who apply to have patients of their own include some of the most mature and intelligent of their year

It has been suggested that the medical student may become confused or embarrassed when the patient tries to discuss sexual problems We have not found that this presents any real difficulty, provided that the topics of discussion at the interview are worked through with the supervisor, and the student's own feelings about them are given some outlet A feeling-tone of shame or embarrassment in the interview situation, if it should become noticeable, can be taken up and analysed objectively It goes without saying that sexual conflict is an important contributory cause of the illnesses that bring patients to the clinic, and knowing something of how to deal with these is a valuable asset to the doctor going out into the world

We have students in their first clinical year, and students in their third year, taking part in case-work There is little to choose in degree of competence, or in emotional reaction, between the two The most important differences are not in terms of phase of clinical progress, but in terms of disposition and attitude In terms of benefit to the patient, the first-year men do just as well What seems to count, in the case-work situation, is less a formal knowledge of psychiatry or medicine than qualities of personality and motivation

The main advantage of case-work is that it gives the student more confidence and more insight, and better comprehension of the diversity and complexity of human illness He becomes more receptive to the " undertones " of communication—" reading between the lines ", as a patient once put it He learns, too, about his own reactions to the ill person, and how these can be recognised and tolerated without threatening his relation with the patient He learns how to handle without agitation the patient who is openly hostile, the patient who is unduly demanding, or theatrical, or flirtatious, the patient who seeks to manipulate the staff of the clinic for his own ends In short, he learns how people behave when they are ill and anxious, and how the illness may be utilised for gain

Open Questions

Of course, there are questions about the place of case-work in the teaching of psychiatry which await answers One such is what is the most appropriate place for it in the curriculum—which of the clinical years? What reading, if any, should be done? There is an argument against absorbing much textbook material before embarking on case-work, that it tends to set up in the student's mind preconceptions about what he should find, and that it tends to foster an " intellectualising " of the task, with the result that the student looks for security in lists and rules rather than in his own judgments of feeling

What is the place of the formal lecture? Our experience has been that lectures, when not illustrated by demonstration of a patient, make less impact on the student's mind than seminars, or teaching with the aid of the one-way screen (Millar 1954) As Millar said, " Meaning must be given to the complex by the simple, to the abstract by the concrete, to generalities by particulars, to concepts by percepts "

Illustrative Case-reports

One example of a successful outcome in the handling of a patient with several stress disorders by a student has been published already (Goldman 1955) Other examples are given here

Case 1—An engineering office worker, aged 27, was an anxious man with palpitations, vomiting, spots before eyes, and a dry skin He was seen in the outpatient department over four months (fifteen sessions) The youngest of seven children, he had been reared in Eire and given no instruction about sex His symptoms appeared only when he was alone or visited a cinema or a church During his sessions at the clinic there gradually came to light strong feelings of guilt over masturbation and nocturnal emissions in adolescence, all this time he believed himself to be oversexed He said that he had been worried about this for a long time, and wanted to get it off his chest After the last session he was much less anxious and preoccupied with his symptoms A few months later he was cheerful and confident and had no complaints

Case 2—A secretary, aged 16, complained chiefly of feelings of unreality, depression, and fear of death She had attended the clinic weekly for about three months and was still attending Her parents have never got on well, and she was on bad terms with her father—he is " always finding fault, and enjoys arguments " She cannot resist an argument either She was inclined to blame her father for the scenes, and to minimise her own part in them She has been going out with boys since she was 11 years old and has no other real interests She indulges in very heavy petting but always stops short of intercourse—she becomes very much aroused but gets frightened One aim of discussion during her sessions has been to improve her relations with her father and promote insight into her own behaviour with him She has also come to recognise how excessive erotic stimulation can provoke tension She is now less depressed, and her sleep is much sounder, the unreality feelings are still present, but she is less concerned about them

Other Studies of Case-work in Teaching

Houston and Allen (1957) describe a clinical programme for second-year students in the department of psychiatry of the University of California

Each student is assigned one psychiatric patient with whom he works voluntarily in his own time in the outpatient department The patient is seen in weekly one-hour interviews through most of the academic year Supervisors are drawn from residents, fellows, and junior psychiatrists, one of these devotes an hour to the student each week " Orientation meetings " are held to discuss the various questions which emerge from the students' work with patients Houston and Allen comment that the supervisors were often surprised at how well the student had done, and felt humble on comparing the student's performance in the doctor-patient relationship with that of a novice clinician in any field

Coleman (1951) says " The objective of psychiatric teaching is to turn out better doctors, not better psychiatrists "

In his department in the University of Colorado two students work as a team in the pædiatric outpatient clinic, one student seeing the mother, and the other the child The interviews are then fully discussed with the psychiatrist The student, as Coleman says, learns to use his own personality resources He believes that it is much easier to teach medical students than graduate residents; the attitudes of the qualified doctor towards the handling of the disturbed patient are already becoming fixed, whereas the attitudes of the student are still being formed

Comments

Balint (1957) said " Illness is a fruitless struggle by the patient to resolve his conflicts, therapy is an attempt by the doctor to intervene in this dynamic process so that a better equilibrium can be attained " The knowledge which the student must acquire if he is to become a fully effective doctor Balint has named " the pathology of the whole person " In this new pathology there must be, as he says, a long chapter devoted to the most important therapeutic agent, the relationship between the patient and his doctor We consider that case-work by the student will give him insight into this all-important relationship that is unlikely to come by reading and observation alone

Preparation of the student for dealing with disorders of emotional origin is of particular importance for those who intend to work in urban communities Finlay et al (1954) estimated that in an urban practice one patient in five who call upon the doctor does so because of a stress disorder

The attitude of the public in general, and of medical students, towards the psychological aspect of illness is changing Suspicion and ridicule are giving place to curiosity, active interest, and a willingness to devote time and trouble to study and work in this field The student is under some handicap when he first comes to deal with patients during his training His natural and human approach to the sick person tends to become overlaid by the attitudes which preclinical teaching may beget—especially an overvaluation of the physical aspects of causation of disease Case-work brings him back into full contact with his chief object of study—the person who is ill It helps him to place the biophysics and biochemistry of medicine in proper perspective

Summary

One method of teaching in psychiatry is the handling of ill and emotionally disturbed people by the medical student himself under supervision

Its advantages and possible hazards are appraised

It offers the student an opportunity for gaining confidence, and insight into the meaning of illness, that may not be so readily acquired in other ways

We are indebted to Prof W S Peart for his interest and help in the preparation of this paper, and to Miss Dorothy Asbury for her contribution to discussions

SENIOR REGISTRARS

THE Ministry of Health has outlined arrangements[1] for the selection of some posts without limit of tenure for senior registrars who have finished their training and have not yet obtained higher appointments[2]

Hospital authorities are asked to submit proposals for designating some senior-registrar posts which will provide responsible work commensurate with that normally expected of a fourth-year senior registrar, and which are within the present total of senior registrars The new posts " must not be regarded as a substitute for additional consultant posts ", and the senior registrars selected will be free to continue to compete for higher appointments

> " In the course of their review of senior registrar posts, Boards may well find that there are posts held by time expired senior registrars which should be held by part-time or whole-time consultants Such findings should be reported with the proposals in respect of special posts "

The Minister will be advised on the proposals by the professional committee which advises him on consultant appointments The future use of posts of this type will depend on the outcome of the study by the working party on medical staffing structure in the hospital service[2]

In filling posts whose designation is approved by the Minister, boards should consider applications only from senior registrars who have completed their four years of training The posts should be advertised, except where the board, after taking account of the advice of its medical advisory committee, is satisfied that the present occupant of the post is the best candidate that would be likely to come forward if the post were advertised Appointments will be of unspecified duration, but the need for the continued existence of a post will be open to review when it falls vacant Remuneration is to be announced later

Before Our Time

THE AUTOBIOGRAPHY OF CHARLES DARWIN *

Charles Darwin's autobiography is a true testament of science, and, although it contains cautionary elements for those endowed with genius and a passion for discovery, it is nevertheless inspiring reading for the young scientist It is a plain record of the life and work of a man who ranks with Newton as the most important of English scientists Charles Darwin told the truth about himself as he saw it, as all diarists and autobiographers must if they wish their records to endure

James Boswell told the whole truth about himself, shamelessly and tediously, because anything that happened to him, James Boswell, was important and worthy of record " Jamie, Jamie," said his father, Lord Auchinleck, sadly, " if ye sullied your breeches ye'd tell the world " Edward Gibbon told the truth about himself (perhaps not the whole truth) because this was the lifelong habit of the historian Charles Darwin had a still higher standard of accurate reporting, for his training, unlike the historian's, was to record the facts elicited by personal observation and experiment

The interest of the subject and the accuracy of the record give it a high place among English autobiographies Although there is in his prose no rhythm and no eloquence, the plain style well matches the simple story He records the ordinary happenings of any man's life with a simplicity which amounts to naiveté For example, of his life in Cambridge as an undergraduate he wrote

> " We sometimes drank too much, with jolly singing and playing cards afterwards I know that I ought to feel ashamed of days and evenings thus spent, but as some of my friends were very pleasant and we were all in the highest spirits I cannot help looking back to these times with much pleasure "

Charles Darwin had no insight into his own personality or into the nature of his chronic invalidism, but his story is told so frankly and so ingenuously that the instructed reader can today learn more of Charles Darwin than he knew of himself

The autobiography was written for his family in 1876, but since it was written at the instance of a German editor, even the modest Charles must have expected that it would one day be published, as indeed it was five years after his death, in the *Life and Letters of Charles Darwin*, edited by his son, Sir Francis Darwin Some passages were then omitted either because they were too harsh in their criticism of individuals, or too frank in their statement of Darwin's views on religion The autobiography was republished here in 1929 and again in America in 1950, but it has not recently been readily available in this country, and although the personality and work of Charles Darwin have been given great attention in the past twenty years, the autobiography has not been widely read.

* The Autobiography of Charles Darwin Edited by his granddaughter NORA BARLOW London Collins 1958 Pp 253 16s

Lady Barlow has then done well to give us a full and accurate transcript of the manuscript which is now in the Cambridge University Library. The restored passages contain nearly 10,000 words and, although they neither enlarge nor correct for us the portrait of Charles Darwin, it is highly satisfactory to have at last the complete text.

It is to be hoped that this reprint, together with the chapter written by Sir Francis Darwin concerning his father's personality and method of work, will soon find a place in one of the cheap editions of the classics. This is the first time, I think, that the Autobiography has been published without the complementary reminiscences of his son, and the loss is great.

This omission must have been the result of considered editorial policy, but it clearly demonstrates that Charles related only half the tale and Francis, with the skill of an artist tempered by the affection of a devoted son, told the rest. In partial compensation we are given several appendices covering 100 pages, including an essay on Charles' attitude to his grandfather, Dr Erasmus Darwin, and another on his controversy with Samuel Butler.

* * *

The outline of the story told in the Autobiography is well known, even by those who have not read it. In it Darwin describes the slow growth of his scientific passion, before he joined the *Beagle* on her five-year voyage his geological studies had begun, but of this time he writes "I should have thought myself mad to give up the first days of partridge-shooting for geology or any other science." After his return to England and his marriage to Emma Wedgwood his research gradually excluded all other interests, except his love for his wife and children. Social life, shooting, literature, music, the meeting of scientific societies, the cultivation of friendship—all these were excluded as the formulation and proof of the great hypotheses increasingly filled his mind. The night brought no escape, with its reiteration of the doings of the day and its plans for the morrow, but relief by day was provided by the newspaper, which he read for himself, and by novels which were read to him each day for an hour and a half by the devoted Emma, who also accompanied him each evening in two games of backgammon. When I wrote in *The Lancet* in 1943 that "four hours' work in the daytime sufficed for the performance of the most important scientific work of the nineteenth century", Sir Arthur Keith wrote to me pointing out that "Darwin's brain was a broody fowl—always sitting on a brood—a 24 hour day, not 4 hours!"

Inherited wealth and chronic ill health were the begetters of this situation so fortunate for science, a situation impossible either for the children of the poor or for the healthy—at least if they carry the burden of guilt which afflicted the sensitive conscience of Charles Darwin. The shawl, which was usually draped over his shoulders, became both for him and his children the badge of invalidism—a distress signal to which the family gave unquestioning and ready response. And the cause of his illness? An autonomic disorder, bred, like other autonomic disorders, by Constitution out of Environment, conceived and nourished by the guilt which resulted from his suppressed hostility to that godlike being his father—all-wise, all-kind, omniscient and omnipotent.

* * *

It was a curious fate that brought this prototype father-idolater into conflict with that prototype father-hater, Samuel Butler. The aggressive expression of Samuel's hatred of Canon Butler did not mitigate his violence towards any other father-figure who treated him with contempt, and Charles' unawareness of his hostility to his own father did not reduce his sensitivity to criticism nor diminish a guilty son's need for consolation and security when attacked. Charles had been at school at Shrewsbury with Samuel's father and an undergraduate with him at Cambridge. Samuel was more than an acquaintance, he had also been a professed admirer of Darwin's scientific work, and it was not until 1877 with the publication of *Life and Habit* that he became openly critical of Darwinism. Charles disdained an adversary whose arguments were not founded on scientific fact, but he could not understand, as he wrote to Huxley, why Butler was "so bitter against" him. How could he know, or indeed care, that he had become an offending father-figure for a rebellious son?

The quarrel arose after the publication in 1879 of Charles' *Life of Erasmus Darwin*, which contained a translation of an essay by Ernest Krause which had originally appeared in the German scientific journal, *Kosmos*. While the book was in preparation Charles sent Krause a copy of Samuel Butler's *Evolution Old and New*, which had just been published, with the hope "that he would not expend much powder and shot on Mr Butler as he really is not worthy of it. His work is merely ephemeral." Krause revised his article and included critical references to the views of Butler, although not mentioning him by name. When the *Life of Erasmus Darwin* was published there was no indication that the original article had been revised or by whom and, worse still, there was a footnote in the preface stating that Mr Butler's book *Evolution Old and New* had appeared since Dr Krause's article was published. Butler asked Darwin for an explanation, Darwin replied that "this is so common a practice that it never occurred to me to state that the article had been modified." Butler, unsatisfied, stated his grievance in a letter to the *Athenæum*. Darwin then remembered what he had forgotten, that he had indeed written a paragraph for inclusion in his book stating that Krause had revised this article, remembered then, too, that at Krause's instance, he had caused this paragraph to be omitted, and perhaps did not recognise, even then, that his footnote to the preface would justify a charge of duplicity by the inflammable Butler.

Comfort in this assault by the unspeakable Butler was provided by the family in no ordinary degree. As Lady Barlow relates, "the exchange of letters to and from Down, some of which were sent to London by road in the Down carriage, with John the coachman waiting to bring back the answers shows how serious was the flutter in the Darwin Dove-cot." Should Charles admit his error and rebut the charge of duplicity or should he ignore contemptuously the "nearly insane" ravings of a scribbler? He was persuaded by the majority of his family and by his powerful friends (Huxley and Leslie Stephen) not to sally forth from his ivory tower, but some of his sons, including the wise and unimpassioned Francis, gave him better advice which was unfortunately rejected. So Butler's resentment smouldered on in his aggressive breast, and although the fires were temporarily damped down by Darwin's death, he himself was to die unaware of the truth.

If these lapses of memory were examples of the provocative art of forgetting, yet another example of Charles curious forgetfulness is given by Lady Barlow. Charles in his autobiography gave the year of his father's death as 1847, it was in fact 1848.

* * *

The edition of the autobiography published in 1929 in the Thinker's Library omitted the pages relating to Robert Waring Darwin, Charles' father. This long studied experimentally by Poiseuille in the 1830s He described experiments with two types of viscometer for studies of apparent viscosity and of adherence The results depended on the nature of the surfaces, the temperature, the rates of shear, and other conditions Since viscosity studies have been made in the past in glass tubes, his findings, especially on fibrin-coated tubes, appear of particular interest According to his concept blood-vessels have a fine porous endoendothelial lining of fibrin, probably a calcium fibrinate, which is produced and maintained continuously throughout life The existence of an immobile or-nearly immobile layer would insure that micro-coagulation processes, such as fibrin deposition and fibrinolysis, as well as other reactions could take place undisturbed on the vessel wall The widely divergent results from blood systems in contact with various surfaces emphasise the importance of knowledge of the nature of the inner lining of blood-vessels *The formation of an immobile layer along the wall of the tube* through which the material is flowing, " wall adherence," has not hitherto been studied with blood systems This adherent layer, may be compared with the immobile portion of the marginal plasmatic zone in the living blood-vessel postulated by Poiseuille From his studies on apparent viscosity and wall adherence, Dr Copley concluded that the proposed endo-endothelial fibrin film may play a part in regulating the width of the immobile layer and constitute a major factor in aiding circulation by increasing the velocity of blood-flow

Dr P H Staple (Medical Research Laboratories, Charing Cross Hospital) presented a paper jointly with Dr A L Copley on biomicroscopic observations of the plasmatic zone in the capillary beds of frogs and Syrian and Chinese hamsters These workers have developed a new method for producing graded variations in the velocity of blood-flow in small vessels This method enabled many of Poiseuille's observations to be confirmed for the first time Furthermore, by the injection of graphite suspensions or of a dye, they were able to establish in the capillary bed of the Chinese hamster's cheek pouch the existence of an immobile layer in contact with the vessel wall as predicted by Poiseuille for blood flowing in vivo

Dr G W Scott Blair opened the discussion on the rheological interpretations of the foregoing papers He discussed the meaning to be attached to the term " viscosity " in blood systems He saw no objection to defining viscosity as shear stress divided by rate of shear, even when this ratio is not constant, provided that this fact is specifically stated

Prof K Weissenberg (Cambridge), a rheologist, discussed the many possible kinds of turbulence and of dilatancy, both of which phenomena have been observed in flowing blood He also stressed the very large number of possible anomalies of flow

Other speakers pointed out that the presence of adherent layers found behind a column flowing down a tilted tube do not necessarily prove the existence of such layers in full tubes In reply, Dr Copley pointed out that the in-vivo evidence was, in itself, conclusive

Prof M H Knisely (Charleston, U S A.) read a paper on observations of the settling of blood-cell masses to the lower sides of vessels of animals and men during pathologic conditions, which was illustrated by a colour motion picture, taken through a horizontally aimed microscope This most fascinating film showed clearly that there was a pronounced gravitational settlement of red cells in vivo, so that of two vertically disposed branches of a vessel the upper might contain pure plasma while the lower was choked by a mass of cells This novel observation, which demands further study, has important pathological implications Professor Knisely claimed that in some cases it seemed most probable that blood-cell masses settle in great numbers and become stationary long before the death of the subject, which they help to cause

In closing the meeting, the Chairman said that he was delighted that so many participants from all over the country and some from abroad had attended He expressed the hope that further meetings on hæmorheology would be organised in other centres

The rheological aspects of the conference are to be reported in *Nature*

In England Now

A Running Commentary by Peripatetic Correspondents

Well, it's all over at last and we're back to normal There were those of us, mind you, that actually enjoyed the bus strike, and we're a bit sad to have these great red bloated monsters edging us over the white line as in days of yore No longer can we pull up our saloon at bus stops and see it filled delightfully with typists, models, apprentice actresses, or, earlier in the day, charwomen, keeping a score of Cars They Have Ridden In, who proudly told us of the Rolls with chauffeur that took no less than 12 of them right into the City My holiest load was a Sister of Mercy hotfoot with Inj Streptomycin, who packed her voluminous robes into the front seat and, for some inexplicable reason, a small roll of lino in the back (for some ceremonial purpose ?) Such was her aura of sanctity that I found myself three miles off my road at her destination without quite realising it but she did invite me back to her mission for coffee Now the strike is over, to offer a lift, though in all Christian charity, might be interpreted as carrying a dark nefarious purpose folk that last week wrestled with each other to squeeze in at my rear door would now fly screaming and dial 999

I'm afraid of these buses now, too Will the animosity towards private lift-givers, built up over the weeks, lead some irascible busman to ram his livid half-inch armour-plated giant into my frail craft ? Perhaps I should buy a pair of spectacles and try to look like Mr Cousins And another thing—I've lost a good excuse for being late It's a peculiarity of mine that my " psychostat " is set just five minutes after everyone else's, which means stumbling over knees at lectures and creeping silently into ward rounds behind the treatment trolley With the magic words " No bus " all was forgiven, if they knew I had a car the password was " shocking jam " Now I've got to fall back on sand in the carburettor and the kids being ill

But, then, I must stop thinking hard thoughts about the busmen, bless them, after all, don't *I* have a pay dispute coming up any day now ?

* * *

I had been admitted for what is euphemistically called a minor operation, and I could not have been better looked after The surgeon was skilful, attentive, and kind, Sister was charming, her nurses highly decorative

The little staff nurse was particularly sweet, but we had a few moments of difficulty when she brought me my first meal in hospital, it was the usual assortment of meat and vegetables and I was just about to start when she returned, in some confusion " I'm sorry," she said, " but I'm afraid I shall have to take that away again, you're not supposed to be eating it—after all, you are a hæmorrhoid, aren't you ? "

Thus, in later years, do we flinch once again under the terms of abuse of our student days, time alters many things but, clearly, to the perceptive observer, character—despite added weight and dignity—does not change

* * *

Queueing for the gallery to see the Moscow Arts Theatre was an entertainment in itself A pleasant, moderately shabby man who joined the queue just behind us started a conversation at once, as though we were old friends We kept our end up pretty well for a time, but quickly got out of our depth as it became evident that he spent every evening of the week in queues and had seen everything in London worth mentioning, as soon as it opened, for several years back I wondered how he earned his living, teaching in a progressive school, perhaps, or could he be a " resting " actor ? Two hardbitten, theatrically orientated women behind him entered the discussion uninvited and completed our annihilation Respectable middle-aged women in correct hats, with the calmly patient expressions of housewives inured to queueing, rubbed shoulders with flighty young creatures who darted out of line at intervals to chatter

Personal Papers

THE VISITING-LIST

As others have done before, our medical dining-club at its February meeting discussed the future of general practice We all have views on this (we are an enlightened lot), but perhaps it's a bit late in the day to expect any very novel opinions on this familiar subject What did startle us was a small collection of *facts* which came out almost accidentally near the end After we'd been talking for some time about what practitioners do, and what they ought to do, someone turned to the family doctor who'd opened the proceedings and said "Tell us what *you* did today What kind of patients did you see?" So he produced his visiting-list, and it surprised us Since it may surprise others, I asked him for a copy of it, with his remarks as he gave them to us Here it is

1 *Varicose ulcer* in a filthy man over 70 No hope of improving the dirty house

2 *Acute bronchitis*—Woman of 74 Lives alone, dependent on neighbours One hour's domestic help daily

3 *Aortic regurgitation*—Man over 70 Arteriosclerosis

4 *Cerebral thrombosis*—Man over 80, nursed by wife also over 80

5 *Furuncle of ear*—Woman in great pain and distress

6 *Carcinoma of vulva*—Recurrence after removal of vulva

7 *Acute bronchitis* in a middle-aged man with pulmonary tuberculosis

8 *Tonsillitis* in a child

9 *Mumps* in a middle-aged woman

10 *Influenza* in a young man

11 *Hæmatemesis* in an imbecile Uncooperative young man, with spastic diplegia, treated at home

12 *Lumbago* in an Army officer To be X-rayed (?) disc lesion

13 *Loss of voice* in a schoolgirl Probably simple laryngitis, to be referred to E N T specialist if no improvement in two weeks

14 *Root pain from osteoporosis* in a woman over 80

15 *Hæmorrhage* in a young pregnant woman Admitted to hospital with premature labour

16 *Gangrene of finger* following crush injury Woman over 80

17 *Acute bronchiolitis* in two children.

18 *Acute bronchiolitis* in a child

19 *Acute bronchiolitis* in a child

20 *Secondary carcinoma of liver*—Resection of rectum three years ago Ascites and œdema of feet Difficult case to manage

21 *Acute bronchiolitis* in a child

22 *Cardiac failure* in a man of 79 looked after by his wife, herself a certifiable melancholic

23 *Pain*, from defective peripheral circulation, in a man of 79

24 *Antenatal examination*

25 *Incarcerated hernia* in a woman over 80 with senile confusion Reduction

26 *Rheumatoid arthritis*—This woman also has auricular fibrillation

27 *Sore throat*—A schoolgirl with pharyngitis

28 *Hypertension and chronic bronchitis* in a middle-aged man

29 *Diphtheria immunisation*—Child's mother could not bring him to surgery

30 *Cut hand*—Man of 87 fell and cut his hand Five stitches

31 *Acute bronchiolitis* in a child

32 *Gastroenteritis* in a baby—12 miles from the surgery

33 *Laryngitis* in a woman

Unusually heavy? About average, he said, for the time of year—there are four doctors in the practice, with about 9000 National Health Service patients and three appointments a garrison, a prison, and a factory February saw the tail of an outbreak of bronchiolitis in young children, which accounts for 6 of those on the list

But of course what is chiefly striking about these patients is that so many of them were old, that so many of them were gravely ill (having passed beyond hope of hospital cure), and that almost all were treated at home—the only one admitted to hospital being the young woman in premature labour, who had already been booked Thanks to consultant opinions and the practitioners' own free access to pathology and X-rays, there was a diagnosis in every case, and this must sometimes have reduced the need for admission

I have never thought it true that the practitioner in this country is forced by circumstances into becoming no more than a clerk and certificator, and now I shall be rather more sceptical when people tell me that general practice concerns itself only with minor illness You too perhaps?

F

Congresses

FLOW OF BLOOD IN RELATION TO VESSEL WALL

A MEETING, sponsored by the clinical research committee of Charing Cross Hospital, to discuss the flow of blood in relation to the vessel wall, was held on June 13 at the Charing Cross Hospital Medical School

Opening the conference, Mr N C LAKE, the chairman, said that it was the first ever devoted exclusively to hæmorheology Although any addition to medical jargon was to be deplored the title "hæmorheology" was justified, for the subject was a vast one of rapidly increasing importance (Hæmorheology is a term introduced by Copley[1] and defined as covering "the deformation and flow—i e, rheological—properties of cellular and plasmatic components of blood in macroscopic, microscopic and sub-microscopic dimensions and the rheological properties of vessel structure with which blood comes in direct contact") Extensions in cardiac and vascular surgery had raised fresh questions which demanded an answer, and the growing incidence of cerebral and cardiac vascular lesions presented new problems for the physicians He then gave examples of the ways in which rheological studies might aid the clinician in his practical work, finally quoting from the preface to James Parkinson's *Essay on the Shaking Palsy* (1817) "That these friends to humanity and medical science, who have already unveiled to us many of the morbid processes by which health and life is abridged, might be excited to extend their researches to this malady, is much to be desired "—a mandate to all research-workers

Dr G W SCOTT BLAIR (Reading), a rheologist, surveyed work on the flow of suspensions through tubes with special reference to blood He pointed out that during the past thirty years two groups of workers have been studying certain deviations from Poiseuille's law of flow almost completely independently of each other Particularly Fahræus and his school in Sweden have worked on blood, whereas many rheologists in quite other fields (e g, paints, clays, plastics) have pursued independent investigations with no knowledge of blood Only recently have the two lines of investigation converged, with much mutual benefit

Dr A L COPLEY (Medical Research Laboratories, Charing Cross Hospital) reported on studies of adherence and viscosity of blood, plasma, and serum in contact with surfaces foreign to blood and with fibrin surfaces His investigations were based on the observations of the plasmatic zone in the living blood-vessel, already known to Malpighi in the 17th century but

---

[1] Copley, A L *J Colloid Sci* 1952, 7, 323

Weary—I think it will be appreciated that these people are putting an abnormal strain on their bodily functions during pregnancy By typifying these women in the film, it is hoped that the expectant mothers will, by their cooperation with their medical advisers, remove these factors of overweight, anæmia, malnutrition, and fatigue which hasten the onset of toxæmia in susceptible subjects

I speak as a practical obstetrician dealing more with people than with statistics and theories, and also as obstetric adviser to the film in question I believe that there is very little substance in Professor Platt's criticism, when related to the purpose of the film For one who is an ardent follower of scientific truth, it is strange that Professor Platt should criticise a film which he has never seen, and of which he has read only a brief account Nevertheless, I look forward to spending a pleasant half-hour with him, showing him the film, and providing some relevant references

GRAVITATIONAL LEG ULCERS IN THE ELDERLY

SIR,—Dr Rivlin is to be congratulated on his very practical article last week. He rightly stresses the importance of the history, for we often depend on this to determine whether the ulcer is varicose or post-thrombotic As he points out, the distinction is useful as it affects treatment and prognosis

Dr Rivlin classified 75% of his series of 200 patients as having varicose ulcers and 15% as post-thrombotic The proportion of varicose ulcers is greater than that found by many workers in recent years, and one wonders whether the name of his clinic attracts a larger number with varicose veins than does a general-hospital clinic dealing primarily with leg ulcers Certainly in my own series the proportions are very different. Of 1676 patients with " venous " leg ulcers (i e, excluding those resulting from arthritis, arterial disease, or other conditions) 1172 (69 9%) gave a clear history of thrombophlebitis of the lower limb with much œdema The thrombophlebitis had been associated with various conditions—post-partum 283, injury to the leg 282, unknown causes 154, medical illness 94, fractured leg 79, ante-partum 70, treatment of varicose veins (usually injections) 70, operation (not on the leg) 61, infection of the leg 37, burns of the leg 27, operation on the leg 15 There were in addition 266 patients with no definite history but whose ulcers were probably post-thrombotic.

It would have been interesting to have had Dr Rivlin's views on arterial factors, especially in the 93 patients over the age of 60 There seems little doubt that arteriosclerosis or hypertension or both may play an important part in the ætiology of gravitational ulcers

I have not calculated the statistical significance of Dr Rivlin's figures showing the results of treatment, but wonder whether there is any significant difference between the varicose and post-thrombotic groups A factor of great importance in the rate of healing is the chronicity of the ulceration before treatment is started

PHYSICAL CHANGES IN THE PROLAPSED DISC

SIR,—Your correspondents Mr Bonnin (June 28), Mr Hendry (June 21), and Mr MacKenzie (June 21) are satisfied that the phenomena we attribute to disorders of the disc can be fully explained by mechanical injuries superimposed on the process of desiccation in disc degeneration They find it unnecessary to invoke any other mechanism such as I have postulated in a transient phase of raised internal disc tension It is easy to explain chronic backache by disc desiccation and to explain some attacks of lumbago and sciatica by analogy with the displacement of a torn meniscus in the knee, but there are other aspects which seem to me to demand a more subtle explanation.

Compare, for instance, the quality of the pain of lumbago with the quality of the pain when a patient displaces a cartilage in the knee After the first twenty-four hours a " locked " knee ceases to cause spontaneous pain and is painful only if the patient fails to rest the limb By contrast a severe attack of lumbago will cause spontaneous agony for two or three weeks and resist bed rest and even injections of morphine This persistent spontaneous pain is unlike the response of the body to a simple mechanical displacement, because skeletal tissues rapidly adapt to a displaced fragment and pain will disappear though it will return if function is demanded of the part. It seems to me that the persistent agony of a severe attack of lumbago is more like the pain caused by raised tension inside cavities which resist distension. An alveolar abscess or a boil in the external auditory meatus causes pain which persists in a way which could not be imitated by inserting a solid object of the same shape and size as the bead of pus, because the tissues which were stretched by the solid object would adapt themselves and only a fluid mechanism capable of continued expansion could maintain the tension and so maintain the pain One of the most painful complications in orthopædic surgery is a postoperative hæmarthrosis after meniscectomy, if bleeding from a small artery fills the closed cavity of the knee-joint with blood under tension the postoperative pain is so severe that no amount of morphine will render the patient completely comfortable nor will any position of the limb afford relief, and this condition will persist until the tension is relieved

One of the most surprising things about acute lumbago is that the amount of pain does not seem to be proportional to the amount of organic change visible in the disc. It is possible for a patient to have a violent attack of lumbago in early adult life and thereafter to have attacks for twenty years without the vertebral bodies adjacent to the disc showing any of the changes we associate with degeneration of the annulus, loss of elasticity, or failure of the hydraulic mechanics of the disc. I find it difficult to explain how a young man can quickly recover athletic perfection after a prostrating attack of acute lumbago if the process is merely a degeneration of the annulus leaving this structure capable of rupture by forces which would not damage a normal disc. Would not a young athlete with a degenerate annulus be permanently debarred from sport ?

Like a number of other surgeons ten or twelve years ago I used to explore cases of acute lumbago on the theory that these were caused by protrusions which had emerged in positions such as the midline where a nerve-root was not directly involved to give the picture which otherwise would be sciatica We rarely found convincing protrusions in these cases, but what is cogent to the present argument is that the material removed appeared more often to be normal than to be fibrous and stringy

I agree with the comment in your annotation of June 7 that one of the difficulties in accepting the hypothesis of raised disc tension is that I have never observed swollen and gelatinous disc tissue at operation I do not think that this is an insuperable obstacle to the theory, because the disc is contained inside a tough casing and the pressure can rise isometrically, without the volume increasing very much In my experiments using the cadaveric disc the gaily to friends up or down the queue One of the latter, her bare feet thrust into sandals consisting of a strip of white leather attached precariously to a sole, had toenails painted startling white to match her skirt Young couples in grubby jeans and shapeless sweaters, the girls mostly without make-up and with hair uncombed, stood seriously waiting, sometimes reading, or eating sandwiches out of battered, grimy shopping bags Arty girls in clean, brightly-coloured sailcloth trousers, wearing dazzling make-up and exotic hair-styles, eyed with faint contempt the nice young teachers dressed in flowered summer frocks and engaged in earnest, clear-voiced conversation A tweedy man who was reading the play of the evening in Russian discoursed on it in a voice unmistakably English to his companion, who was also English and tweedy The sound of elderly foreign voices recalling the Moscow Arts Theatre of many years ago mingled with the bored tones of slightly supercilious bowler-hatted youths talking about nothing in particular Soon small boys from nearby flats casually took up positions near the queuers who happened to be eating, and occasionally turned cartwheels or terrorised each other in the intervals when they were not hopefully rushing to open the doors of taxis arriving at the stalls entrance An air of expectancy was heightened by the cheerful, bent little man selling souvenir programmes with a maximum of sales-talk

We did not see any obvious doctors in the queue I wonder what we looked like ourselves?

* * *

In our hospital N A D, I D K, M S U, and other concise contractions help us in the labour of form-filling Now I've met the giant of abbreviations, acromegalic and ponderous in its proportions The X-ray request card simply read as follows "F H N H I U D ?" What *could* it mean? "Frightened hectic nurse has injured upper denture?" No "Fœtal heart not heard Intra-uterine death?"

* * *

A youngish woman came to me about a compensation claim She had given up work as a waitress some months ago and had just been taken on in a new job, for which she was to receive a course of special training which would last for one week She would then become a cosmetic consultant Evidently there are no registrar problems in the beauty parlours

GAY NIGHT IN A G P's LIFE

11 P M —Receive request to visit Mrs J in her home

11 30 P M —Visited Mrs J, who has lately arrived from West Indies Diagnosed acute appendicitis and advised removal to hospital and made necessary arrangements with E B S

MIDNIGHT —Went to bed

1 50 A M —E B S rang to say they had been advised by ambulance team that mother refused to go to hospital unless her baby went with her and they believed the baby to be only 3 weeks old I advised E B S that baby was nearly 4 months old and could safely be left at home

2 A.M —E B S rang again to say that hospital would not admit the baby I asked them to try other hospitals

2 15 A M —E B S rang again and asked me to call again at patient's house to sort things out.

2 25 A M —Arrive at patient's house again Baby was 15 weeks old, but apparently there was no-one left at home during day to look after it. I drove to local hospital but could not persuade them to alter their minds about admitting baby Returned home, rang another hospital who agreed to admit mother and baby I advised E B S of this and I returned to bed

4 15 A.M —Hospital rang to advise me that Mrs J had taken her discharge almost immediately after admission as (*a*) she felt better, and (*b*) an immediate operation was not to be performed I took no further action

6 30 A M —Night bell rang At front door was Mrs J's husband He told me his wife was much worse and in great pain Would I arrange readmittance to hospital This I did

9 A.M —Start day's work.

Letters to the Editor

N H S. STAFF COLLEGE

SIR,—No amount of legislation or official exhortation can of itself bring together in harmony the three parts of our Health Service

The fullest personal exchange of views at all levels would produce results beneficial to the family doctor, the hospital staff, and the medical officer of health, and through them to the patient

Both industry and many of the leading professions find it advisable to establish central training and liaison units There are staff colleges for the four Defence Services, for bankers, Civil Servants, hospital administrators, and even for trade unionists

Is it not now time to set up a National Health Service Staff College where every sort of problem could be examined dispassionately? Not only the formal aspect of the work but also the private discussions which follow give value to this form of conjoined study

Health Department,
Brighton

W S PARKER
Medical Officer of Health

TIME AND THE NURSE

SIR,—Last year you said "If hospitals were to make it the rule that temperature, pulse-rate, and respiration-rate were to be recorded only if specifically requested by the clinician, nurses would have more time for more important techniques, and their proper work of nursing the sick"[1] When a "hospital" makes a "rule" of this sort, who is the "hospital"? I have been told that in some hospitals your practical suggestion is difficult to put into effect because the medical committees are reluctant to agree to it

Although your suggestion would save much time, its implementation would probably be made easier if it could be demonstrated, in a manner acceptable to medical and to nursing committees alike, not only that routine temperature, pulse-rate, and respiration-rate recordings are of little value but also that the dropping of them is, as you imply, to the advantage of patients as well as nurses No real nurse would wish to save time in this way if the patient were to suffer

Secondly, there are legal considerations would the abolition of this routine mean that the ward-sister must accept legal responsibility for failing to take the recordings exceptionally on her own initiative? If so, routine might prove a cheap form of insurance

Thirdly, what would be the effect on the patient public? Maybe many feel that this routine procedure provides an important opportunity for regular personal contact between patient and nurse, what other regular opportunities are envisaged in the "proper work of nursing the sick" to which you refer?

An important time-saving suggestion of this nature merits thorough investigation

JOHN CHARNLEY

BILIARY VESICULAR STASIS

SIR,—I am delighted to see, in Mr Dudfield Rose's article last week, a more critical attitude towards biliary surgery, as with modern methods of investigation the time has long passed when blind cholecystectomy should be performed for obvious or presumed diseases of the biliary tract

I have no personal experience of manometry, which is especially popular with French surgeons However, serial cholecystograms and especially operative cholangiography are imperative in order to reveal conditions which might otherwise be overlooked Operative cholangiography is a simple and often illuminating procedure, which I have used in over 1000 cases, and I regard it as an essential investigation in an elective cholecystectomy [1]

Mr Rose emphasises that reflex spasm of the sphincter of Oddi is a clinical entity, but he does not mention that a pathological appendix can cause reflex hypertonic vesicular stasis, and in early cases—i e , before the muscle becomes fibrotic—biliary symptoms disappear after appendicectomy

Owing to the disappointing results of blind cholecystectomy no investigation should be omitted which may help in unravelling the complex conditions which affect the biliary tract, and " repeat " operations are not only disappointing to the patient, but are likely to tax the skill and patience of any surgeon

London, W 1

McNEILL LOVE

THE OUTPATIENT DEPARTMENT

SIR,—I was glad to see your annotation of May 10, and I agree with Dr Emslie and Dr Fry

To Dr Fry's three main roles of the outpatient department—consultation, diagnostic, special investigation and treatment centre—I would add a fourth that of teaching centre for undergraduates and postgraduates, as illustrated in a contribution to the Widdicombe File [2] some years ago

As you remark, much capital needs to be devoted to improving the outpatient department, but there is another no less urgent investment, and that is *in men* The outpatient department requires no less adequate staffing than the ward Greater good would be done to more patients if the best physicians spent more time in outpatients, where there is the greater challenge, and less time at the bedside

Seven years ago the Hadassah Medical Organisation inaugurated Medical Outpatient Department C, staffed by full-time physicians In this unit, 18,000 patients have been treated There are 2000 visits a month, including 200 by new patients 12 patients a month are referred for medical admission and 5 more patients to the surgical wards Many patients are saved the need of hospital beds, and patients who cannot be admitted, or who refuse admission, are often able to get essential treatment in outpatients Undergraduates and postgraduates find there a representative cross-section of the world of practice There are also special problems, such as how to treat patients living in bad environments, and how best to supplement the training of younger doctors in the outpatient department

Outpatient work of a high standard requires (1) physicians whose first interest is in the patient, (2) time to listen and to examine and to answer the patient (which means adequate staffing), (3) consultative services in the specialties, (4) laboratory and radiological services, (5) good records and records office, (6) recovery-observation beds, (7) research work based on the outpatient

The success and prestige of an outpatient department depend on the active presence of senior staff and their encouragement by the administration and, in a teaching hospital, by the Faculty

A good outpatient department is an expensive undertaking, but without it health services cannot be run economically, efficiently, or humanely

TIME AND THE NERVOUS SYSTEM

SIR,—I fully sympathise with Professor Russ's difficulty (expressed in his letter last week) in grasping " Professor Woodger's definition of Time " because there is no such thing, and the non-existent is notoriously difficult to grasp Let us hope that there will always be no such thing What was offered was a definition of " clock "—which is quite a different matter Confusing " time " with " clock " is like confusing " space " with " foot-rule "

I was glad to see Professor Russ's reference to Robb, because Robb's work has been sadly neglected—perhaps because it appeared (if memory fails me not) at the beginning of the first world war But it does not do Robb justice to say that " he proposed that Time is simply a matter of ' before ' and ' after ' " What he did was to construct axiomatically a theory of spatiotemporal relations which he called the theory of Conical Order In this he introduced the notion of *after in time* as an undefined notion In my first attempt to use the axiomatic method in biology (1937) I used *before in time* as an undefined notion If you have either of these the other can be defined as its converse Surely before and after are not attributes as Professor Russ calls them but relations, and in that case what can it mean to speak of " the span between them " ? It is only the terms which stand in these relations to one another that can have (some of them) a span between them, and that span is itself a term in the relation

Department of Biology, Middlesex Hospital
Medical School, London, W 1

J H WOODGER

THE PLACE OF HUMAN BIOLOGY IN *MEDICAL EDUCATION*

SIR,—I am bound to agree with Dr Scott (June 21) that Dr Tanner's suggested preclinical curriculum (June 7) seems rather long and rather diffuse And I agree with Dr Scott again that much of our present trouble can be traced to the unreal and misleading separation of anatomy, physiology, and pathology As he says, the important thing is that anatomy and physiology should be understood, not merely memorised They cannot really be understood in isolation from one another, nor can pathology be understood in isolation from physiology and anatomy

A similar attitude should in my opinion be adopted towards physics, chemistry, and biology I do not think that the student will " for all practical purposes have done enough at school " He may have done enough to gain exemption from 1st M B , but he will not have done enough to understand these subjects and their bearing on his later studies Just as Dr Scott recommends that anatomy and pathology should run through the whole curriculum and on into postgraduate work, so should our knowledge and understanding of the basic sciences be enlarged by constant references to them throughout our working lives Thus we may better understand what we are trying

---

1 Love, McN *Brit J Surg* 1952, 40, 161
2 *Lancet*, 1954, ii, 420

to do in the course of our medical practice. Thus we can move more and more towards scientific medicine and away from empiricism. (There should be no more need than there is at present to introduce a course of instruction on the humanist aspect of our work.)

Perhaps I should add that I write in all humility as one who daily regrets his lack of grasp of the subjects he "learnt" for 1st and 2nd M.B.

How right Dr Scott is about teaching! The art of great teaching must certainly be restored to its proper place. But there are not many great teachers, and they stand out under all circumstances. It is also important that those who like teaching should be encouraged to do it, and that teaching should not be regarded as a chore but as one of the highest of human activities.

R. R. WILSON

COLOURED TABLETS

SIR,—Mr Grainger (June 21) must be aware that green tablets, which are seventh on his list of degree of attraction to children, have been far and away the most frequent cause of accident—I refer to the green tablets of ferrous sulphate.

Surely Mr Grainger is being less than fair to the British Pharmacopœia Commission in his second paragraph. The statement in the introduction to the *B.P. 1958* on the use of colour in tablets is as follows:

> "Permission has been given in a limited number of monographs on tablets for the addition of a suitable colouring agent to the coating because unfortunately uncoloured tablets have not been made available."

This permission in any case applies only to a few coated tablets and not to the majority of tablets contained in the *B.P.*

PREMEDICATION FOR OUTPATIENT ELECTROCONVULSION THERAPY

SIR,—Dr Collard's letter of June 21 is of interest at this time when we are concerned in making electroplexy as safe a procedure as possible.

In my limited experience of both general-hospital and mental-hospital practice, I have found that resistance among patients to pretreatment usually responds to simple explanation and sympathetic reassurance.

Before recommending premedication in addition to thiopentone and relaxants it might be worth while bearing in mind certain points which Dr Collard does not mention.

(*a*) That cumulative and/or synergistic effects of premedication plus thiopentone and relaxants might be expected to cause an increase of respiratory depression and postconvulsive apnœa.

(*b*) That there might perhaps be an increased number of subshocks received by the patients, which in themselves, although not harmful, might necessitate either stepping up the voltage or a greater number of attendances for the patient in order to produce satisfactory remission, and in the event of increasing the voltage, the possibility of neuronal damage being produced in some patients—e.g., recurrent endogenous depressives—who may require several courses of treatment.

(*c*) Whether premedication diminishes postconvulsive confusion, which in my experience is complained of more by patients than pretreatment anxiety.

In view of the fact that the use of thiopentone and relaxant drugs for electroplexy has been associated with an increase of mortality, it is desirable to adopt a critical attitude towards the addition of what may be a further risk to the patient, unless the results of properly controlled experiments show otherwise.

St James's Hospital,
Leeds

MARSHALL FRIEZE

NEW LIGHT ON MOLLUSCUM SEBACEUM

SIR,—May I be allowed to comment on your interesting leading article of June 7? The red margin of the lip is a site on which these tumours may arise, though the idea that they can occur here had been resisted by those who believed in the pilosebaceous origin. Since I published my first case,[1] "kerato-acanthoma of the lower-lip red margin", I have collected others. Spontaneous regression was noted and shown in the published photographs, and was complete. To fit in with the theory of origin the red margin of the lip should contain pilosebaceous follicles. According to the anatomists the lips, though hairless, may contain sebaceous glands. Do these show cyclical activity?

Cambridge.

C. HOWARD WHITTLE

ANÆSTHESIA FOR THE EMPHYSEMATOUS

SIR,—In your annotation of June 14 you discuss the special difficulties of anæsthesia in the presence of respiratory insufficiency and state:

> "Unfortunately there is as yet no simple way of estimating the gas tensions of arterial blood, but, if metabolic alkalosis can be excluded, the serum-bicarbonate content of venous blood will indicate whether or not carbon-dioxide retention is present."

In our experience this simple test may be seriously misleading if given the interpretation you suggest. In the accompanying table we give the blood-gas findings in four patients suffering from moderate to very severe CO_2 retention following anæsthesia and surgery.

Case	Time	Plasma				Blood
		T CO_2 (mM per l)	H_2CO_3 (mM per l)	pH	pCO_2 (mm Hg)	O_2 satn. (%)
1	Immediately postop	30·8	28·3	7·15	83	93
2	Immediately preop	37·0	34·8	7·29	75	70
	Postop	34·9	30·5	6·94	147	85
3	Postop	24·1	20·0	6·79	137	42
4	3 hr postop	30·4	26·4	6·92	133	90

Of these patients, cases 1, 3, and 4 almost certainly had normal electrolytes and blood-gas tensions before operation. Despite severe CO_2 retention their plasma-T CO_2 and bicarbonate levels remained within the normal range. Case 2 had emphysema and elevated T CO_2 before operation. Postoperatively the T CO_2 had fallen slightly. This was not associated with improvement in the CO_2 retention but with serious aggravation of it.

The reason why the plasma-T CO_2 fails to rise to the levels expected in severe CO_2 retention is that anæsthesia itself, especially if there is anoxæmia, is associated with metabolic acidosis which depresses the level of plasma bicarbonate. The resulting level of plasma-T CO_2 is therefore a balance between two influences working in opposite directions.

This problem cannot be resolved by making one measurement on blood. Two measurements are necessary: the blood-pH and the plasma-T CO_2. The former estimation can be done in a few minutes with modern techniques, and therefore we suggest that your final sentence should have read: "Few will dispute that facilities for determining the blood-pH and plasma-T CO_2 level should nowadays be available to the anæsthetist."

Surgical Unit,
St. Mary's Hospital,
London, W 2.

HOOKWORM AND ANAEMIA

SIR,—Dr Meiklejohn and Dr Passmore (April 19) suggest that diet is the main factor in the anæmia associated for so long with hookworm infestation in the tropics I would agree with Sir Philip Manson-Bahr (May 3) that diet has little if anything to do with the anæmia

Among tea-garden labour in Assam we see a good deal of anæmia even though the malarial type is now almost extinct When patients who are investigated and found to have hookworm infestation alone are treated for this the improvement is dramatic with no alteration in diet, and they are indeed treated as outpatients so that there can be no change

As regards the financing of further research, I would point out that the Indian Tea Association financed a long and extensive survey carried out by Dr Foy and Dr Kondi in 1955 on the causes of anæmia in Assam, and their conclusions coincided with the less expert opinion of the tea-garden doctors that is, that hookworm was one of the causes, be it only one, of the many that are found in this area

EFFECT OF PREDNISOLONE ON VITAMIN-B_{12} ABSORPTION IN PERNICIOUS ANÆMIA

SIR,—While studying lactic dehydrogenase (LD) activity in various forms of megaloblastic anæmia, I came across the interesting paper by Doig et al [1] on the response of megaloblastic anæmias to prednisolone I have now observed that vitamin B_{12} not only causes hæmatological remission but also restores to normal the increased LD values found in pernicious anæmia Later, I found that the LD activity also responded to prednisolone

Four cases were studied two patients with pernicious anæmia in relapse, one with pernicious anæmia in remission, and one non-anæmic patient who had had a total gastrectomy for peptic ulcer The results were as follows (the oral dose of B_{12} given in the Schilling test was 1 µg B_{12}-^{60}Co, and an excretion of 2 5% has been regarded as the upper limit in pernicious anæmia)

	Schilling test	
Condition	*After prednisolone*	*Prednisolone discontinued, B_{12} given parenterally*
Pernicious anæmia in relapse	8 8%	1 7%
Pernicious anæmia in relapse	8 6%	3 9%, later 3 1%
	Before prednisolone	*After prednisolone*
Pernicious anæmia in remission	0 1%	2 8%
Total gastrectomy	0 3%	0 4%

Thus, in two patients with pernicious anæmia, who showed improvement of the blood-picture and restoration of the bone-marrow to normal after prednisolone therapy (30 mg daily for 21 days), the Schilling test values also became almost normal When the effect of the prednisolone had subsided and adequate antianæmic therapy had been instituted, the Schilling values fell below normal In the first case a fæcal excretion test (oral dose 1 µg B_{12}-^{60}Co) showed practically normal values (62 8%) after prednisolone

In the third case (pernicious anæmia in remission), where the response to the Schilling test was much decreased before prednisolone therapy (30 mg daily for 7 days), a significantly increased value was obtained after prednisolone By contrast, the patient who had had a total gastrectomy did not respond to prednisolone, as revealed by the Schilling test

These preliminary results suggest that the remission that follows the giving of prednisolone is due to increased absorption of vitamin B_{12}, which in turn may be attributable to an increase in the production of intrinsic factor caused by the prednisolone It should be emphasised that the absence of a response in the gastrectomised patient points in the same direction, since in this case cells capable of producing intrinsic factor were lacking

In both cases of manifest pernicious anæmia responding to prednisolone, there was a definite rise in the microbiological serum-B_{12} level during prednisolone therapy (63 to 125 µµg per ml and 46 to 134 µµg per ml, respectively) This also supports the assumption that the remission may have been due to absorption of small amounts of vitamin B_{12} from the intestine

"A BARE BODKIN"

SIR,—Francis Bacon said that "death will not be denied", William Hunter commented, "How easy and pleasant a thing it is to die", and Hamlet's famous soliloquy refers to the simplicity with which life can be ended I believe that some articles, such as those of Bedford,[1 2] give, perhaps, an unnecessarily gloomy view of the capacity of the human body, however aged, to withstand "the thousand natural shocks That flesh is heir to" The following case is reported in support of this thesis, and because complete recovery from a number of severe cardiovascular accidents at the age of 92 is worthy of record

The patient was a farmer who, at the ripe age of 92, was admitted to hospital under the care of my colleague, Dr J Charles Shee, on May 19, 1957, following a severe hæmatemesis, for which he received transfusions amounting to 8 pints of blood in the first instance He had been most unwilling to enter hospital for treatment, as he had never been ill before, and felt that he would recover more quickly at home on his farm in the bush Surgical opinion was not sought at this time, since his doctor did not think that surgery was likely to be helpful in so old a patient

Medical treatment seemed to have been entirely successful, but the patient suffered a further hæmatemesis on May 21 which necessitated transfusion of 3 pints of blood I first met the patient on May 24, when he had had another severe hæmatemesis I reached the bedside in response to an urgent summons, to find a cheerful old gentleman, "a man not old, but mellow, like good wine", whiter than the sheet, with obvious evidence of a massive hæmatemesis, receiving blood through veins in both arms, and glucose solution through his right long saphenous vein Even this did not seem to be adequate to replace the amounts he had lost and was losing His cardiovascular age seemed, however, to be less than his chronological age, for in spite of his shocked condition he was sufficiently alert to lay down a most exact therapeutic regimen in the whispered words, "Cut me quick, Doc, or I'm a goner"

This succinct assessment of the situation was so patently correct that the operation began less than thirty minutes later Laparotomy disclosed a large gastric ulcer astride the left gastric artery about 2 in below the œsophagogastric junction Fortunately, although a chronic ulcer, it had not penetrated any other viscus, and a rapid partial gastrectomy was comparatively easy to perform The left gastric artery was controlled as early as possible, and his condition improved considerably as soon as this step had been completed

His condition at the end of the operation was fairly good, and he made good progress until the second postoperative day, when he seemed very shocked This was due to the onset of auricular fibrillation, which was controlled within forty-eight hours by digoxin He then made an uninterrupted recovery until seven days later, when he complained of severe upper abdominal pain, and once again looked *shocked and ill* This setback was due to a moderate-sized anterior myocardial infarct, which responded to treatment

---

[1] Bedford, P D *Lancet*, 1956, ii 750
[2] Bedford, P D *ibid* 1957, ii, 505

From this time onwards, his condition never gave rise to any anxiety, and he left hospital on June 20, in excellent general condition, and with his fibrillation controlled

Recently, he sent me a present of some biltong, prepared from a buck which he had shot to celebrate his 93rd birthday, surely adequate confirmation of the completeness of his recovery

The main interest of this case is its demonstration of the recuperative powers of such an aged patient, following two severe and one torrential hæmatemeses, auricular fibrillation, and a myocardial infarct, all within the space of some fourteen days In spite of all these serious insults to his cardiovascular system, and the stress of a major surgical procedure, he made a complete recovery, thereby demonstrating, once again, that " a man is as old as his arteries "

I should like to express my thanks to Dr J Charles Shee for his help in the management of this patient, both before and after operation, for without his skill the patient would not have survived At least an equal tribute must be paid to Dr Ian Michie, who administered the anæsthetic

Bulawayo, Southern Rhodesia. WILLIAM HOUSTON

DEATH OF A BOXER

SIR,—In reference to Dr Compton Smith's letter last week, I cannot recall any cases of cerebral injury or indeed meeting any punch-drunk boxers in my long association with both amateur and professional boxing Injuries can of course take place if a man cannot defend himself, but the trained referees of the A B A and B B B C in consultation with their medical advisers are always vigilant to prevent men entering the ring in an unfit condition of health They are also quick to stop a contest if a man is badly outmatched and suffering any serious injury before or during the fight

Tunbridge Wells E F ST J LYBURN

AUTO-ANTIBODIES IN THYROID CARCINOMA

SIR,—It is now well established [1] [2] that antibodies which precipitate with thyroid extracts can be demonstrated in the serum of patients with lymphadenoid goitre

In testing sera of patients with various thyroid disorders, we found that three out of six cases of thyroid carcinoma had high titres of antithyroglobulin when examined by the tanned-cell hæmagglutination test In two of them, the level of antibody was sufficiently high (titre of 20,000) to give a positive precipitin test by the Oudin method

In the first of these two cases biopsy showed anaplastic carcinoma and areas histologically resembling lymphadenoid goitre In the second case, treated by hemithyroidectomy, examination of many blocks of the excised lobe showed replacement of all normal thyroid tissue by papillary carcinoma (no tissue was available from the remaining lobe, which appeared slightly enlarged but otherwise normal) The third case had a titre of 640 in the tanned-cell hæmagglutination test and the Oudin test was negative Examination of the thyroid gland revealed both anaplastic carcinoma and lymphadenoid goitre

The clinical distinction between thyroid carcinoma and lymphadenoid goitre may be difficult, and until recently the ultimate diagnosis often depended on microscopic examination of the gland Abnormal flocculation reactions or positive precipitin tests may now be taken to favour a diagnosis of lymphadenoid goitre, but, judging by our experience, the finding of positive serological (precipitin) tests does not justify a firm diagnosis of lymphadenoid goitre unless there is other strongly suggestive clinical or biochemical evidence Lymphadenoidal goitre may well predispose to the subsequent development of carcinoma, and the two conditions may be present together Although surgery is now seldom indicated as a definitive form of treatment for lymphadenoid goitre, surgical assistance should be freely invoked to establish a certain diagnosis

THE TOURNIQUET

SIR,—I congratulate you on your leading article of May 31

I hold it very necessary to popularise, among surgeons, the aversion towards that horrible medieval instrument that is the tourniquet In this sense, I go much further than Professor Pannett, since I use neither the tourniquet nor any other kind of temporary hæmostasis for any limb operation—not even for amputations [1] I believe that the immediate and late complications of amputation have thereby been avoided—especially stump neuralgias and phantom limbs Progress after operations on bone, nerve or tendon has been excellent The systematic hæmostasis introduced, step by step, during the operation, maintains a normal blood-supply and avoids the serious disturbance caused by ischæmia and reactional hyperæmia

Barcelona M BASTOS ANSART

TETANUS

SIR,—In a leader in your issue of May 10 it was suggested that Hippocrates gave the first description of tetanus and of its usually fatal outcome However, the remarkable author of the Edwin Smith papyrus (19th century B C) (which is thought to be a copy of an earlier work, possibly dating back to the building of the Pyramids —i e , to the 30th century B C [2]) describes the following clinical picture

Examination If thou examinest a man having a gaping wound in his head, penetrating to the bone (and), perforating the sutures of his skull, thou shouldst palpate his wound, (although) he shudders exceedingly Thou shouldst cause him to lift his face, if it is painful for him to open his mouth, (and) his heart beats feebly, if thou observe his spittle hanging at his two lips and not falling off, while he discharges blood from both his nostrils (and) from both his ears, he suffers with stiffness in his neck, (and) is unable to look at his two shoulders and his breast

First diagnosis Thou shouldst say regarding him "One having a gaping wound in his head, penetrating to the bone (and) perforating the sutures of his skull, the cord of his mandible is contracted, he discharges blood from both his nostrils (and) from both his ears, while he suffers with stiffness in his neck An ailment with which I will contend "

Second examination If then, thou findest that the flesh of that man has developed fever from wound which is in the sutures of his skull, while that man has developed ty' (untranslatable) from that wound, thou shouldst lay thy hand upon him Shouldst thou find his countenance is clammy with sweat, the ligaments of his neck are tense, his face is ruddy, his teeth and his back (?) the odor of the chest of his head is like the BKN (urine) of sheep, his mouth is bound, (and) both his eyebrows are drawn, while his face is as if he wept

Second diagnosis Thou shouldst say regarding him " One having a gaping wound in his head, penetrating to the bone, perforating the sutures of his skull, he has developed ty', his mouth is bound, (and) he suffers with stiffness in his neck An ailment not to be treated " ?

Third examination If, however, thou findest that that man has become pale and has already shown exhaustion

Third treatment Thou shouldst have made for him a wooden brace (or tube) with linen and put into his mouth

*Gloss B** As for "The cord of his mandible is contracted", it means a stiffening on the part of the ligaments at the end of his ramus, which are fastened to his temporal bone, that is at the end of his jaw, without moving to and fro, so that it is not easy for him to open his mouth because of his pain

---

[1] Bastos Ansart, M Tratado de Operatoria Ortopedica y Traumatologica. Barcelona, 1957

[2] Husein, K. *J Bone Jt Surg* 1949, 31B, 309

* These are glossaries given in the original papyrus as explanatory notes to the text. They were probably written by later copyists

Gloss E As for "The ligaments of his neck are tense" it means that the ligaments of his neck are stretched stiff by reason of his injury

Gloss I As for "His mouth is bound, (and) both his eyebrows are drawn, while his face is as if he wept", it means that he does not open his mouth that he may speak, both his eyebrows are distorted, one drawing upward, the other drooping downward, like one who winks while his face weeps

This gives a very objective description of trismus, neck rigidity, and risus sardonicus (?), following a wound of the head, and ending fatally The phrase "an ailment not to be treated" meant in old Egyptian texts a fatal outcome, in contradistinction to "an ailment I shall treat" and "an ailment with which I will contend" which were used to signify a good and a doubtful prognosis respectively

The possibility that this description meant meningitis cannot, of course, be excluded The necessity of placing a wooden brace (or tube) between the teeth and the other signs make it very likely, however, that it meant tetanus

DIETARY RESTRICTION AND COAGULABILITY OF BLOOD

SIR,—I read with great interest the article by Dr McDonald and Miss Edgill in your issue of May 10 We reported in our letter of Feb 8 the results of our investigations on hypercoagulability and "heparin loading test" As we had pointed out,[1–3] our "heparin loading test" can reveal hypercoagulability

In patients with hypercoagulability, the level of cholesterol, total lipid, and phospholipid were increased and at the same time there was an increase of β-lipids and a decrease of α-lipids in lipidograms

In cases showing hypercoagulability according to the heparin loading test, three to six months of strict low-fat diet with or without anticoagulant treatment, hypercoagulability decreased or became normal (50 mg heparin twice weekly intravenously) Further details will be published later

The remark of Dr McDonald and Miss Edgill about the parallel between the cholesterol level and platelet-stickiness is of considerable importance

We, too, have observed[3 4] the connection between the blood-lipid level and platelet function

In the course of our studies[3–5] of the hæmorrhagic diathesis in liver diseases, we drew attention to the fact that when cholesterol and cholesterol esters were much diminished, α-lipids almost disappeared and β-lipids decreased, whereas the agglutinability and adhesiveness of the platelets were much reduced or lost and the bleeding-time was prolonged

At the same time, there was a large reduction in the formation of thromboplastin (Biggs and Douglas's test) due to a defect in platelet suspension The platelets did not contain the thromboplastic factor (phospholipid) in other words, a secondary thrombopathia was observed[3] in liver disorders

As Dr McDonald and Miss Edgill have shown, and our observations have confirmed, there is a close relationship between the level of blood-lipids and platelet functions

TREATMENT OF ASTHMA AND HAYFEVER BY HYPNOSIS

SIR,—I studied with great interest Dr Mason and Dr Black's case-report in your issue of April 26 I especially admired the thoroughness and objectivity of the presentation

Apparently without realising it, they submitted this patient to one form of conventional "desensitisation" therapy—namely, the parenteral administration (either subcutaneously or intradermally), co-seasonally, of very minute amounts of pollen extracts This method of treatment is extremely effective in all patients with pure pollen allergy, and is especially effective when preceded by a course of relatively high-dosage therapy, which, I presume, is what the patient actually had (during the previous season)

A very interesting clinical feature is the "cold in the head", contracted during the "second week of June" This episode was undoubtedly allergic in nature, especially in view of the specific response to ephedrine It probably occurred between the clinic visits of week 7 and week 8, if we assume that week 1 was represented by April 29 *What is interesting is the fact* that during the two visits immediately preceding (weeks 6 and 7), she was given intradermal injections only in the left arm, whereas on all of the other visits, if we consider only the span of the height of the pollen season, she was given injections in the left leg as well as the left arm In other words, for weeks 6 and 7 she received only *half* the usual dosage It is entirely possible that this half dosage was slightly less than this patient's particular requirement for this particular pollen season If so, the accumulated deficiency of two weeks' underdosage could well explain the allergic symptoms described as a "cold in the head"

Nevertheless Dr Mason and Dr Black have made an important contribution—namely, their demonstration of the relationship between psychomotor factors and skin reactivity And this, after all, is the main theme of the article, judging by its title

We have continually noted that, in any given group of patients, there is a remarkable lack of correlation between the relative severity of clinical symptoms and the relative intensity of skin reactions For example, one patient may have very weak (although perhaps highly specific) skin reactions, but very severe *clinical symptoms* Another patient may have very strong skin reactions with very mild clinical symptoms

This same lack of correlation is observed whether or not the patient has had any "desensitisation" therapy Some patients who have been clinically cured by "desensitisation" therapy will nevertheless *retain their skin reactivity*, at least to some definite degree On the other hand, some patients will have relatively rapid diminution of skin reactivity early in the course of treatment, even though their clinical symptoms may not yet be under control

This quantitative dissociation between skin reactivity and clinical symptoms has been a source of many misunderstandings and much confusion Many explanations have been offered by various investigators, but they usually add to the confusion

The observations of Dr Mason and Dr Black lend some objective evidence, which, if properly interpreted and followed up, may help to lead us out of our bewildered state Their observations suggest that, even though skin reactivity is specifically related, *qualitatively*, to clinical allergic manifestations, the actual *intensity* of the skin reactions may be strongly influenced by purely psychomotor factors

On the other hand, they have not proved anything conclusive about the relationship between psychomotor factors and clinical allergic manifestations In fact, on the basis of the data given, we cannot conclude that psychological treatment played any important role whatsoever in relieving the allergic symptoms of the patient.

There is no question but that hypnosis, and other forms of psychiatric treatment, occupy an important and very respectable place in the treatment of allergic disease, but I seriously doubt if the psychiatric approach will ever justifiably assume the dominant role

The only notable exception might be in the neurotic adult patient, who has recovered from a severe childhood allergy, but whose strong "psychiatric residual" causes him, under certain circumstances, to re-enact certain "allergic" symptoms In such a case, the psychiatric factor is unquestionably dominant, and hypnosis could very well be the most effective treatment. However, contrary to general opinion, such cases are surprisingly uncommon.

For the vast majority of patients with atopic allergy there is not, as yet, any substitute for the following principles of treatment

(1) *Avoidance of the offending antigen or antigens* —This is imperative in all cases of food allergy, and all cases of "environmental" allergy (house dust, feathers, animal danders, &c)

(2) *Control of infection* —Acute or chronic bacterial infections, involving any organ or system of the body, will usually aggravate atopic allergy manifestations, even though the latter may be expressed in an entirely different organ or system Prompt treatment with antibiotics is generally indicated

(3) *"Desensitisation" treatment* —This is often a very important aspect of the treatment of "environmental" allergy, although not necessarily so in small children and infants It is the only effective treatment for pollen allergy, regardless of the patient's age

Chief of Allergy Service.

U S Army Hospital, Paris

METHOD FOR THE ASSAY OF PROPERDIN

SIR,—The work of Pillemer et al[1] with properdin showed the important role of aspecific factors in natural resistance to infection and illustrated the interesting interactions of this principle with the components of the C′ It can now be said that both these points have been confirmed[2-6] Some difficulties are met, however, in carrying out the assay of properdin, as proposed by the discoverers of this factor It has therefore been suggested that properdin activity be measured by other methods based on different principles (hæmolysis of tanned cells, bacteriolytic activity, &c) Our experience has not, however, been entirely satisfactory with these procedures

In recent months we have tested a new method for the estimation of properdin with better results The principle is that described by Pillemer et al[1] which uses a polysaccharide prepared from yeast cells—zymosan

Our technique entails careful absorption of the sample of properdin by double incubation at 17° C with a standardised amount of inulin, an insoluble polysaccharide which has some advantages over zymosan[3] Serial dilutions of the properdin-inulin complex are then incubated for one hour at 37° C with a fixed amount of RP (properdin-free serum) formed from the supernatant of the tube previously incubated at 17° C, and 1 ml of sensitised cells is added

The optical density of hæmolysis, read photometrically, is inversely proportional to the properdin value The C′3 titre of the sample under examination is each time determined by R3 (C′3-free serum) Controls are necessary to ascertain total absorption of properdin and the reliability of the other reagents

With this procedure it is possible to overcome some difficulties of Pillemer's method for the preparation of suitable RP As is known, only a few sera (5–10%) prove useful for the preparation of RP The RP prepared from the sample under examination is a good reagent for the properdin determination of the same serum On the other hand, in the procedure here outlined the C′3 activity of the system is precisely determined, while in Pillemer's method no reference is made to the C′3 titre of the sample test

We have performed more than 60 properdin determinations with constant and reproducible results In normal subjects properdin varies within narrow limits The value is lower in older than in young people Research on sera in pathological conditions is now in progress

GLUCURONIDE SYNTHESIS IN FŒTAL LIVER AND KIDNEY

SIR,—Glucuronides are synthesised in adult liver by enzymic transfer of glucuronic acid from uridine diphosphate glucuronic acid (U D P G A) to an acceptor substance,[1,2] which can be bilirubin[3] It is known that certain newborn jaundiced infants are unable to transfer glucuronic acid to bilirubin in this manner[4]

Recent work,[5] using *o*-aminophenol and (−)-menthol as acceptor substances, has shown a similar defective transference to be characteristic of fœtal liver and kidney in the guineapig, mouse, and probably other species In the liver, and possibly in the kidney, the phenomenon is explained by deficiency of both the enzyme (U D P -transglucuronylase) and U D P G.A Levels of both increase up to birth, and it seems that the amount of liver U D.P G A available is to some extent a limiting factor That the same microsomal enzyme is being studied as the one transferring glucuronic acid to bilirubin is probable from the reduced synthesis of both phenyl and bilirubin glucuronides in congenitally jaundiced adult humans and rats[6]

By the kind cooperation of Prof J Walker and the staff of the department of midwifery, Queen's College, two normal human fœtuses of 3–4 months were studied by this method In both, negligible amounts of liver enzyme and U D P G A , or of kidney glucuronide formation, were found Results were also negative for placenta

It may be that certain types of neonatal jaundice are due to persistence of this fœtal metabolism, particularly in premature infants Administration of U.D P G A might therefore prove of use, where its lack is the limiting factor, but there seems no explanation of the claimed relief of this condition by oral treatment with glucuronate,[7] an ion which does not increase the enzyme action in vitro[1] Attempts to induce glucuronide formation by administration of glucuronidogenic drugs could lead, in cases of low U D P -transglucuronylase, to competition with bilirubin at the already deficient enzyme molecules

TREATMENT OF ASTHMA AND HAYFEVER BY HYPNOSIS

SIR,—I studied with great interest Dr Mason and Dr Black's case-report in your issue of April 26 I especially admired the thoroughness and objectivity of the presentation

Apparently without realising it, they submitted this patient to one form of conventional "desensitisation" therapy—namely, the parenteral administration (either subcutaneously or intradermally), co-seasonally, of very minute amounts of pollen extracts This method of treatment is extremely effective in all patients with pure pollen allergy, and is especially effective when preceded by a course of relatively high-dosage therapy, which, I presume, is what the patient actually had (during the previous season)

A very interesting clinical feature is the "cold in the head", contracted during the "second week of June" This episode was undoubtedly allergic in nature, especially in view of the specific response to ephedrine It probably occurred between the clinic visits of week 7 and week 8, if we assume that week 1 was represented by April 29 What is interesting is the fact that during the two visits immediately preceding (weeks 6 and 7), she was given intradermal injections only in the left arm, whereas on all of the other visits, if we consider only the span of the height of the pollen season, she was given injections in the left leg as well as the left arm In other words, for weeks 6 and 7 she received only *half* the usual dosage It is entirely possible that this half dosage was slightly less than this patient's particular requirement for this particular pollen season If so, the accumulated deficiency of two weeks' underdosage could well explain the allergic symptoms described as a "cold in the head"

Nevertheless Dr Mason and Dr Black have made an important contribution—namely, their demonstration of the relationship between psychomotor factors and skin reactivity And this, after all, is the main theme of the article, judging by its title

We have continually noted that, in any given group of patients, there is a remarkable lack of correlation between the relative severity of clinical symptoms and the relative intensity of skin reactions For example, one patient may have very weak (although perhaps highly specific) skin reactions, but very severe clinical symptoms Another patient may have very strong skin reactions with very mild clinical symptoms

This same lack of correlation is observed whether or not the patient has had any "desensitisation" therapy Some patients who have been clinically cured by "desensitisation" therapy will nevertheless retain their skin reactivity, at least to some definite degree On the other hand, some patients will have relatively rapid diminution of skin reactivity early in the course of treatment, even though their clinical symptoms may not yet be under control

This quantitative dissociation between skin reactivity and clinical symptoms has been a source of many misunderstandings and much confusion Many explanations have been offered by various investigators, but they usually add to the confusion

The observations of Dr Mason and Dr Black lend some objective evidence, which, if properly interpreted and followed up, may help to lead us out of our bewildered state Their observations suggest that, even though skin reactivity is specifically related, *qualitatively*, to clinical allergic manifestations, the actual *intensity* of the skin reactions may be strongly influenced by purely psychomotor factors

On the other hand, they have not proved anything conclusive about the relationship between psychomotor factors and clinical allergic manifestations In fact, on the basis of the data

Notes and News

A NEW POLIOMYELITIS CENTRE

ON June 25 the Earl of Limerick, chairman of the Medical Research Council, opened the laboratory buildings of the poliomyelitis centre which is being set up at the Hendon Isolation Hospital, London. Lord Cottesloe, the chairman of the North West Metropolitan Regional Hospital Board, recalled that in 1951 the Poliomyelitis Committee of the Royal College of Physicians of London, under the chairmanship of Sir Charles Symonds, had suggested that a research unit was needed for the investigation of problems concerned with the established disease, and donations of £12,000 from the National Fund for Poliomyelitis Research and of £8000 from the Sir William Coxen Trust had now enabled the laboratory to be built.

As it was thought essential that research should be carried out during the infectious stage of the disease as well as later, it was decided to build the centre at an infectious diseases hospital in close touch, geographically and administratively, with an orthopædic hospital. On the recommendation of Mr H J Seddon, who was responsible for the planning of the centre, Hendon Isolation Hospital was chosen. Over many years the hospital has worked in close cooperation with the Royal National Orthopædic Hospital at Stanmore, and the secondment of nurses and physiotherapists from Stanmore to Hendon will ensure that patients are looked after by the same staff at the two hospitals. Dr A B Kinnier Wilson, a Medical Research Council worker, already attached to the Royal National Orthopædic Hospital where he was working on respiratory problems in poliomyelitis, is now in charge of the laboratory at Hendon, supported by a number of clinicians. If work on poliomyelitis comes to an end the situation of the centre and its link with the Virus Reference Laboratory at Colindale make it a suitable place for the investigation of other virus disorders affecting the nervous system.

The Institute of Orthopædics of the University of London is responsible for the affairs of the centre, but because of its intimate connection with the Hendon Isolation Hospital a coordinating committee has been appointed on which members of the regional medical service, as well as of the Institute of Orthopædics and Royal National Orthopædic Hospital, will serve.

The building is of ingenious design. It is inexpensive and made of a Malayan hardwood called keruing which is as hard as teak, has excellent insulating properties, and needs neither paint nor other preservative. The laboratory was designed by Mr. Lindsay Drake, A.R.I.B.A., of Fry, Drew, Drake, and Lasdun, with the aid of Mr Michael Smythe, A.R.I.B.A., of the Nuffield Foundation.

A FAMILY GUIDE

THE family of a patient who has had a mental breakdown are often frightened and unhappy. They are faced with an illness which they do not understand and therefore fear. Though they are anxious to help, they are uncertain how best to do so. They may feel cut off from the patient by the change that has come over him, they may feel cut off from their neighbours by an unreasonable feeling of shame. Though the healthy and growing change in the public attitude towards mental illness is steadily easing many of these difficulties, there still remains room for the useful guide for the patient's family which the National Association for Mental Health have published.[1]

In the course of relating the story of Jim Thomas who had a mental breakdown, and Alice his wife who had to cope, the booklet gives a clear and honest description of our mental health services and procedure for admission to hospital. It does not suggest that they are perfect, but it makes clear that they can offer help and the hope of recovery to most patients. If community treatment is to prove as successful as we all hope, the family will play an increasingly important part in the patient's treatment, but home is not necessarily the best place for the patient at every stage of his illness. The guide gives a good description of life in hospital, from the point of view of the patient and his relatives, and explains that the family should not feel guilty for arranging for the patient to go there, their turn will come later in helping him to adjust himself to normal life again after he returns home.

Illness, mental or physical, must throw a burden on any family. This guide will help the families of the mentally ill to shoulder theirs with confidence and courage.

AN OPERATING-THEATRE SPOTLIGHT

Mr P Dawson-Edwards and Dr W N Vellacott write:

One of us (P. D-E.) has twice recently described parallel-beam spotlights which it was considered could be made "at home" by hospitals with engineers willing and able to undertake this type of work.[1] The majority of hospitals, however, are probably not in this position, and a commercial firm was therefore approached with a view to the production of such a spotlight. This lamp is now on the market.

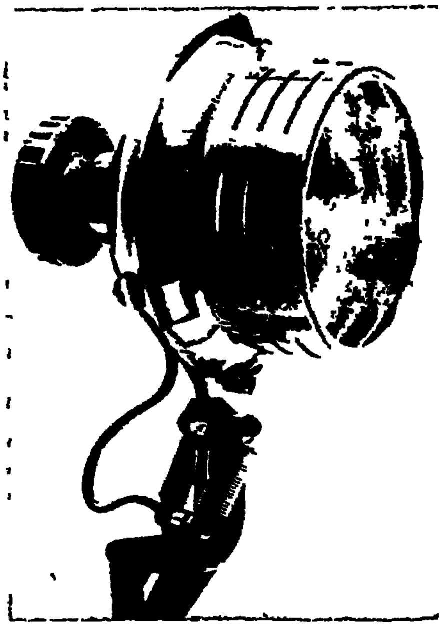

Fig 1—Close-up of lamp showing easily detachable filter holder

It is basically the smaller Lucas "Flamethrower", a lamp noted for its extremely powerful parallel beam. To ensure that the beam is virtually "cold", it is made to pass through a disc of Chance's ON 20 glass, which filters out 90% of the heat and yet transmits 90% of the light. This filter is mounted in a slotted holder which spaces it from the lamp, thus allowing it to be cooled on both sides. The holder is neatly clipped to the lamp housing and can readily be removed for cleaning by releasing the two retaining screws on the front of the lamp (fig 1). An aluminium bulb-shield ensures that there is no dazzle except in the direct line of the beam. The use of a special axial coiled coil bulb provides an even pattern of light of 7 in. diameter which never requires refocusing.

The lamp is mounted on a specially designed 'Anglepoise' arm which makes adjustment both easy and positive through an almost universal range of movement. A plastic handle is fitted to direct the beam. The anglepoise arm can itself be swivelled on the main column. The base of this column, suitably weighted, contains a 12-volt transformer. The finish is in cream with chromium-plated lamp and fittings, and the wheels are of the regulation conducting type (fig 2).

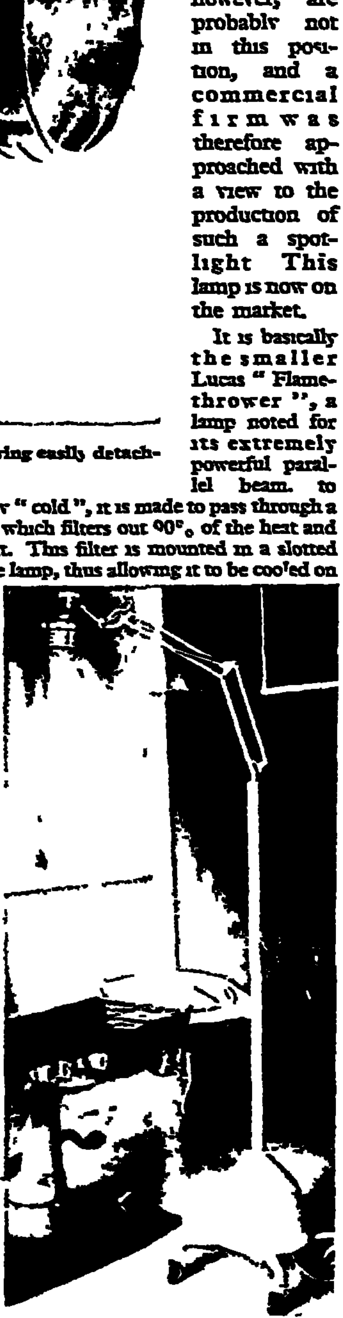

Fig 2—Complete lamp showing base with fully enclosed transformer

---

[1] Mental Breakdown. 1958 Pp 28 2s 6d Obtainable from the Association, 39, Queen Anne Street, London, W 1, postage 4d.

[1] *Lancet*, 1955, i, 849, *ibid* 1957, ii, 525

The lamp has been thoroughly tested It has been found particularly helpful in operations deep in the thorax, the abdomen, or the pelvis, it is usually best used in conjunction with normal overhead lighting, and sometimes only for quite short periods during an operation It has also found favour with ophthalmic surgeons, and it has been in constant use in casualty departments The spotlight is always in focus, is very bright, and is astonishingly easy to manœuvre

This spotlight may be obtained from Messrs Herbert Terry and Sons Ltd, Redditch, or their agents

University of London

The board of governors of Queen Charlotte's Hospital and the Chelsea Hospital for Women have set aside £50,000 of their endowment funds for the endowment of a chair of obstetrics and gynæcology at the Institute of Obstetrics and Gynæcology

University of Leeds

At recent examinations the following were successful

M B, Ch B—Margaret Barber, Pauline Bittner, Norman Carr, Frank Carter, Margaret E Coles, A J K Dore, M W Flowers, Gillian M Foster, R D Jackson, J N Lambton, P B Pickles, Stanley Sorkin, Freda M Tomlinson, B K Turnbull, R K Wright

D P M—John Blackburn, Margaret W Galley, Mary Jones, H B Kidd, J T Rose, Brian Ward

University of Liverpool

Dr K McCarthy and Dr K R Dumbell have been appointed senior lecturers in bacteriology, and Dr J L Braithwaite and Dr E W Macmillan senior lecturers in anatomy

University of Manchester

At a recent examination the following were successful

M B, Ch B—J W Aspinall, Roy Battye, F H Brindle, D B Brookes, J E Brooks, A L Buckley, Eric Charles, P J Cox, J S Cumming, Barry Deakin, B H Delany, G G Duckworth, R M Flinn, Joyce Harris, Roy Haworth, Patricia A Hegarty, Raymond Holmes, Alexander Hopkins, W H Isbister, Maria Z Kozubowska, R J Lawton, I P McEwan, A C Peterson, J D Rhodes, P H Roberts, Martin Ryan, Elizabeth M Spencer, Roy Statham, Garo Tahta, Peter Watson, J M Watts, B K Wignall, J D G Williams, S K Wood, P B Wrigglesworth

Queen's University, Belfast

Dr T K Marshall has been appointed to a lectureship in pathology (forensic medicine)

Royal College of Surgeons of England

Faculty of Anæsthetists—Dr G S W Organe has been elected dean of the faculty for the coming year, and Prof E A Pask vice-dean

Royal College of Physicians of Edinburgh

Dr Jessie Macgregor prize for medical women—An award of this prize, competition for which is open to women who are graduates in medicine of the University of Edinburgh or who have taken the Scottish triple qualification, will be made in November to the applicant who presents the best record of original work in the science of medicine Applications must reach the Convener of Trustees, Royal College of Physicians, 9, Queen Street, Edinburgh, 2, by Oct 31

British Association of Urological Surgeons

The following have been elected officers and members of council for 1958–59

President, Mr Arthur Jacobs, immediate past-president, Mr R H O B Robinson, vice-president, Mr Hugh Donovan, hon treasurer, Prof V W Dix, hon secretary, Mr J D Fergusson, hon editorial secretary, Mr N M Matheson, members of council, Mr F R Kilpatrick, Mr W S Mack, Mr T J Millin, Mr R A Mogg, Mr D S Poole-Wilson, Mr N L Shepperd, Mr J Swinney, and Mr D Innes Williams, and (ex officio) the president of the Section of Urology of the Royal Society of Medicine and the chairman of the editorial committee of the *British Journal of Urology*

International Congress on the Modern Educational Treatment of Deafness

This congress will be held at the University of Manchester from July 15 to 23 Further particulars may be had from Mr D M C Dale, department of education of the deaf, the University, Manchester, 13

British Medical Association

Dain Fund—During 1957–58 the Fund has spent £2300 in grants, helping 23 cases including 7 new ones Nearly every child needs help over a period of years, and, as school fees are mounting and the help required increases, subscribers are asked to continue their support and to enlist the support of others

---

Dr J A Fraser Roberts has been elected president of the Royal Anthropological Society

Dr Brian MacMahon has been appointed professor of epidemiology at the Harvard School of Public Health

Dr Alex Comfort and Dr D S McLaren are among those who have received this year Ciba awards for research on the problems of ageing

A meeting of the Society for General Microbiology will be held in the University of Liverpool on Sept 18 and 19 Further particulars may be had from Dr B W Lacey, department of bacteriology, Westminster Medical School, London, S W 1

Caution—be Warned in Rhyme—Mr Edmund Quarry, the editor of *Better Health*, has for the past ten years offered his readers pills of good advice in the jam of light verse His good-natured admonishments have now been collected in a small book (London Hodgetts Pp 65 4*s* 6*d*) which he has illustrated himself

CORRIGENDUM *Billy Goes to Hospital*—We apologise to Prof R S Illingworth and to those readers who were perplexed by last week's reference (p 1399) to his article "on another page of this issue" Our note about the Guy's booklet was to have appeared with Professor Illingworth's paper, which will be published soon

THE ROLE OF ENDOGENOUS PYROGEN IN THE GENESIS OF FEVER *

W Barry Wood, Jr
M D Johns Hopkins
PROFESSOR OF MICROBIOLOGY

From the Department of Microbiology, Johns Hopkins University School of Medicine and School of Hygiene and Public Health, Baltimore, Maryland

The view that fever and inflammation are intimately related is more than a hundred years old In 1851 Zimmermann[48] suggested that fever might be caused by products of inflammatory lesions His suggestion received prompt support from a number of investigators, who succeeded in preparing from purulent exudates a variety of extracts which, when injected intravenously, produced fever[13 19 24 45] In the light of subsequent evidence it is significant that at least some of these early preparations were relatively resistant to heat

Pyrexin

In 1943 Menkin[32] separated from inflammatory exudates a pyrogenic euglobulin fraction which he later named "pyrexin" It too was heat-stable, even when boiled, it retained its full activity[33] In this regard it resembled bacterial pyrogens[8] More recent studies have revealed that pyrexin has many of the other properties of pyrogenic bacterial endotoxins[10] Like them, it produces fever only after a relatively long latent period when injected intravenously, it causes an appreciable leucopenia after the injection, it induces a state of refractoriness, known as tolerance, when administered repeatedly†, and its pyrogenic effect is much depressed when it is injected into animals previously made tolerant to other bacterial pyrogens Indeed its resemblance to bacterial pyrogens is so striking that Menkin[34] concludes that pyrexin may be a "complex" of bacterial pyrogen with serum-globulin

Leucocytic Pyrogen

Five years after Menkin's report, a fever-producing substance with very different properties was extracted from polymorphonuclear leucocytes by Beeson[8] Unlike pyrexin and bacterial pyrogens, the leucocytic pyrogen was eventually found to have the following properties (1) it was relatively heat-labile[10], (2) it caused a briefer febrile response (after a relatively short latent period)[10], (3) it caused little, if any, post-injection leucopenia[10], (4) it was fully active in recipients tolerant to bacterial pyrogens[8], (5) it did not produce tolerance when repeatedly injected[10], and (6) it was, at least to some extent, species-specific in its action[36]

This last property is of particular interest in relation to Menkin's original experiments Whereas he demonstrated that pyrexin extracted from inflammatory exudates in dogs was pyrogenic to rabbits, Petersdorf and Bennett[36] find that the pyrogen contained in canine leucocytes is inactive in rabbits Clearly, leucocytic pyrogen and pyrexin are two different substances

The accompanying table shows that each of the characteristic properties of pyrexin is common not only to bacterial pyrogens but also to the toxic polysaccharides extracted chemically from normal tissues by Landy and Shear[30] In contrast, none of these properties is shared by leucocytic pyrogen

Transferable Pyrogen

In 1953 Grant and Whalen,[21] studying the pyrexial response of rabbits to typhoid vaccine, detected in their sera, as long as three hours after the injection of the vaccine, a component which produced fever when injected intravenously into a second set of rabbits Having shown that typhoid vaccine previously incubated with normal rabbit plasma caused the same kind of prompt response as that induced by the transferable pyrogen, they concluded that the latter was formed by an interaction of the originally injected bacterial endotoxin with the plasma

Two years later Atkins and Wood[1 2] showed that the transferable pyrogen detected by Grant and Whalen[21] was quite separate from bacterial endotoxin Whereas the endotoxin was rapidly cleared from the blood-stream, the transferable pyrogen persisted throughout the febrile response, and its concentration in the circulation was directly proportional to the intensity of the fever[2] The newly discovered factor appeared to be endogenous and was biologically indistinguishable from leucocytic pyrogen (see table)

COMPARATIVE PROPERTIES OF PYROGENS

Pyrogen	Stability to heat *	Relative length of latent period	Post-injection leucopenia	Activity when injected into tolerant recipients	Production of tolerance	Action on thermoregulatory centres when in circulation
Bacterial endotoxins[8]	Stable[8]	Long[8]	Marked[8]	Depressed[8]	Yes[8]	Indirect[8] †
Pyrexin[33]	Stable[33]	Long[10]	Marked[33]	Depressed[33]	Yes[10]	§
Chemically extracted tissue polysaccharides[30]	Stable[30]	Long[30]	Marked[30]	Depressed[30]	Yes[30]	§
Leucocytic pyrogen[8]	Unstable[10]	Short[10]	Slight or none[10]	Unaffected[10]	No[10]	Direct[27]
Pyrogen in circulation during endotoxin-induced pyrexia[2]	? ‡	Short[2]	Slight or none[2]	Unaffected[2]	No[21]	Direct[7]
Pyrogen in circulation during febrile phase of acute bacterial infections[21]	? ‡	Short[21]	§	Unaffected[21]	§	Direct[1]

* Exposure to 90 C for 30 minutes
† Action may be 'direct' when endotoxin is in spinal fluid.[28]
‡ No satisfactory method has been developed for testing heat-stability of pyrogen in presence of serum.[21]
§ Not yet tested.

---

* The studies from the author's laboratory which are referred to in this article were supported by a grant from the Life Insurance Medical Research Fund They were made in collaboration with Elisha Atkins, M.D., of the department of medicine, Yale University School of Medicine, New Haven, Connecticut, and M Kenton King, M D, of the departments of medicine and preventive medicine, Washington University School of Medicine, St Louis, Missouri

† Menkin's (1955) finding that pyrexin, when given in large enough doses, does not produce tolerance, does not invalidate the earlier observation[19] that it does so when given in smaller doses It has been clearly established that tolerance to bacterial pyrogens may be wholly masked, if the doses used in the repeated injections are sufficiently large[38]

The lamp has been thoroughly tested It has been found particularly helpful in operations deep in the thorax, the abdomen, or the pelvis, it is usually best used in conjunction with normal overhead lighting, and sometimes only for quite short periods during an operation It has also found favour with ophthalmic surgeons, and it has been in constant use in casualty departments The spotlight is always in focus, is very bright, and is astonishingly easy to manœuvre

THE ROLE OF ENDOGENOUS PYROGEN IN THE GENESIS OF FEVER*

W Barry Wood, Jr
M D Johns Hopkins
PROFESSOR OF MICROBIOLOGY

From the Department of Microbiology, Johns Hopkins University School of Medicine and School of Hygiene and Public Health, Baltimore, Maryland

The view that fever and inflammation are intimately related is more than a hundred years old In 1851 Zimmermann [48] suggested that fever might be caused by products of inflammatory lesions His suggestion received prompt support from a number of investigators, who succeeded in preparing from purulent exudates a variety of extracts which, when injected intravenously, produced fever [13 19 24 45] In the light of subsequent evidence it is significant that at least some of these early preparations were relatively resistant to heat.

Pyrexin

In 1943 Menkin [32] separated from inflammatory exudates a pyrogenic euglobulin fraction which he later named "pyrexin" It too was heat-stable, even when boiled, it retained its full activity [33] In this regard it resembled bacterial pyrogens [8] More recent studies have revealed that pyrexin has many of the other properties of pyrogenic bacterial endotoxins [10] Like them, it produces fever only after a relatively long latent period when injected intravenously, it causes an appreciable leucopenia after the injection, it induces a state of refractoriness, known as tolerance, when administered repeatedly†; and its pyrogenic effect is much depressed when it is injected into animals previously made tolerant to other bacterial pyrogens Indeed its resemblance to bacterial pyrogens is so striking that Menkin [34] concludes that pyrexin may be a "complex" of bacterial pyrogen with serum-globulin

Leucocytic Pyrogen

Five years after Menkin's report, a fever-producing substance with very different properties was extracted from polymorphonuclear leucocytes by Beeson [3] Unlike pyrexin and bacterial pyrogens, the leucocytic pyrogen was eventually found to have the following properties (1) it was relatively heat-labile [10], (2) it caused a briefer febrile response (after a relatively short latent period) [10] (3) it caused little, if any, post-injection leucopenia [10] (4) it was fully active in recipients tolerant to bacterial pyrogens [6], (5) it did not produce tolerance when repeatedly injected [10], and (6) it was, at least to some extent, species-specific in its action.[36]

This last property is of particular interest in relation to Menkin's original experiments Whereas he demonstrated that pyrexin extracted from inflammatory exudates in dogs was pyrogenic to rabbits, Petersdorf and Bennett [36] find that the pyrogen contained in canine leucocytes is inactive in rabbits Clearly, leucocytic pyrogen and pyrexin are two different substances

The accompanying table shows that each of the characteristic properties of pyrexin is common not only to bacterial pyrogens but also to the toxic polysaccharides extracted chemically from normal tissues by Landy and Shear [30] In contrast, none of these properties is shared by leucocytic pyrogen

Transferable Pyrogen

In 1953 Grant and Whalen,[21] studying the pyrexial response of rabbits to typhoid vaccine, detected in their sera, as long as three hours after the injection of the vaccine, a component which produced fever when injected intravenously into a second set of rabbits Having shown that typhoid vaccine previously incubated with normal rabbit plasma caused the same kind of prompt response as that induced by the transferable pyrogen, they concluded that the latter was formed by an interaction of the originally injected bacterial endotoxin with the plasma

Two years later Atkins and Wood [1 2] showed that the transferable pyrogen detected by Grant and Whalen [21] was quite separate from bacterial endotoxin Whereas the endotoxin was rapidly cleared from the blood-stream, the transferable pyrogen persisted throughout the febrile response, and its concentration in the circulation was directly proportional to the intensity of the fever [2] The newly discovered factor appeared to be endogenous and was biologically indistinguishable from leucocytic pyrogen (see table)

COMPARATIVE PROPERTIES OF PYROGENS

Pyrogen	Stability to heat *	Relative length of latent period	Post-injection leucopenia	Activity when injected into tolerant recipients	Production of tolerance	Action on thermoregulatory centres when in circulator
Bacterial endotoxins [8]	Stable [8]	Long [8]	Marked [8]	Depressed [8]	Yes [8]	Indirect [2] †
Pyrexin [32]	Stable [33]	Long [10]	Marked [33]	Depressed [18]	Yes [10]	§
Chemically extracted tissue polysaccharides [30]	Stable [30]	Long [30]	Marked [30]	Depressed [30]	Yes [30]	§
Leucocytic pyrogen [3]	Unstable [10]	Short [10]	Slight or none [10]	Unaffected [15]	No [10]	Direct
Pyrogen in circulation during endotoxin-induced pyrexia [2]	? ‡	Short [2]	Slight or none [2]	Unaffected [2]	No [39]	Direct [7]
Pyrogen in circulation during febrile phase of acute bacterial infections [28]	? ‡	Short [1]	§	Unaffected [28]	§	Direct [28]

* Exposure to 90 C for 30 minutes
† Action may be 'direct' when endotoxin is in spinal fluid.[3]
‡ No satisfactory method has been developed for testing heat-stability of pyrogen in presence of serum.[23]
§ Not yet tested.

---

* The studies from the author's laboratory which are referred to in this article were supported by a grant from the Life Insurance Medical Research Fund They were made in collaboration with Elisha Atkins, M.D, of the department of medicine, Yale University School of Medicine, New Haven Connecticut, and M Kenton King, M D, of the departments of medicine and preventive medicine, Washington University School of Medicine, St Louis, Missouri

† Menkin's (1955) finding that pyrexin, when given in large enough doses, does not produce tolerance, does not invalidate the earlier observation [10] that it does so when given in smaller doses It has been clearly established that tolerance to bacterial pyrogens may be wholly masked, if the doses used in the repeated injections are sufficiently large.[23]

Cell-injury Hypothesis

These findings, taken in conjunction with the fact that bacterial endotoxins have both an affinity [15] and a toxicity [14, 29] for leucocytes, led to the suggestion that endotoxin-induced fever is due to the activation of thermoregulatory centres of the brain by circulating endogenous pyrogen released from leucocytes injured by the endotoxin [2] The relatively long latent period and the post-injection leucopenia, which are regularly observed in endotoxin fever,[8] appear to be in keeping with this hypothesis Recently, Bennett, Petersdorf, and Keene [12] have reported that the formation of circulating endogenous pyrogen, which follows the intravenous injection of endotoxin, is greatly depressed in animals previously made leucopenic with nitrogen mustard This finding also supports the suggestion that the endogenous pyrogen is of leucocytic origin

Possible Direct Action of Endotoxin

Certain other facts relating to endotoxin-induced fever, however, have led Bennett and his co-workers [5, 12, 38] to question the validity of this " cell-injury theory " They have justifiably emphasised that a fever-producing factor indistinguishable from leucocytic pyrogen is present in virtually agranulocytic exudates obtained from rabbits made leucopenic with nitrogen mustard [10] They have also shown that such leucopenic rabbits exhibit the usual febrile response to intravenously injected endotoxins,[11] even though circulating endogenous pyrogen is not detected in their blood-streams [12, 37] Furthermore they have shown by ingenious experiments that endotoxin injected intrathecally in minute amounts promptly causes pyrexia [25], that it does not cause tolerance if given repeatedly by this route [25], and that, if given intravenously in sufficiently large amounts, it will " spill over " into the spinal fluid [12] Having thus apparently dissociated the febrile response from the presence of circulating endogenous pyrogen, and having demonstrated that endotoxin in the spinal fluid is highly pyrogenic, they have postulated that the endotoxin itself may play a direct role in causing the fever [12, 38]

As mentioned elsewhere,[27, 28] these observations relating specifically to endotoxin fever must be interpreted with caution The evidence that endotoxin when introduced into the subarachnoid space will cause fever, apparently by acting on the central nervous system, is certainly conclusive That intrathecal endotoxin should have this effect is not surprising in view of the well-known sensitivity of the thermoregulatory centres to noxious stimuli [41] However, it should be emphasised that, after the intravenous injection of endotoxin, an apparent dissociation of the fever and the presence of circulating endogenous pyrogen has been achieved only by injecting relatively large doses of endotoxin under conditions in which the production of endogenous pyrogen is known to be depressed—i e , in the presence of either tolerance or profound leucopenia [12, 38] Furthermore, the failure to demonstrate circulating endogenous pyrogen by the passive transfer technique [1] does not necessarily indicate that it is absent, for the test, as usually applied, is capable of detecting only relatively large amounts of the endogenous factor [26] Sufficient endogenous pyrogen, for example, may be present in the blood of the endotoxin-injected (donor) animal to cause it to have fever, even though the amount transferred to a second (recipient) animal is insufficient to produce a febrile response Although in special circumstances intravenously injected endotoxin, given in sufficient amount, may reach the spinal fluid and thus initiate pyrexia,[12, 38] the data so far obtained do not negate the original observation that in normal animals capable of producing full amounts of endogenous pyrogen, the fever induced by moderate intravenous doses of endotoxin is directly related to the concentration of endogenous pyrogen in the blood-stream [2]

Pyrogenic Tissue Polysaccharides

The isolation of pyrogenic polysaccharides from various normal tissues by Landy and Shear [30] raises the additional question whether these substances may not somehow be involved in the production of fever At present it can only be stated that, since the biological properties of bacterial pyrogens and of the tissue polysaccharides have been shown to be the same [30] (see table), all the arguments against the direct action of the former pertain also to the latter If for no other reason than that they cause tolerance, it seems unlikely that the tissue polysaccharides, at least in the form isolated by Landy and Shear,[30] are directly responsible for natural pyrexia Were the causal pyrogen in the circulation capable of producing tolerance, pyrexia due to systemic disease could not be expected to be fully sustained for more than a few days It is conceivable, however, that tissue polysaccharides may eventually be shown to be released during cellular injury and, when so released, to cause the production of endogenous pyrogen There is as yet no evidence either for or against this interesting possibility

Source, and Site of Action of Endogenous Pyrogen

While the above-mentioned investigations of Bennett et al were in progress, further studies were undertaken relating to the source and the site of action of endogenous pyrogen Polymorphonuclear leucocytes were found to be the principal source of endogenous pyrogen in granulocytic exudates and were observed to discharge their pyrogenic component into the surrounding medium while still motile and apparently otherwise functionally intact [26] Both the endogenous pyrogen derived from leucocytic exudates and that present in the serum during endotoxin-induced fever were also found to exert their pyrogenic effects, when introduced into the circulation, by acting directly on the thermoregulatory centres of the brain [27] Circulating bacterial (exogenous) pyrogen, on the other hand, was shown to act by a different and less direct mechanism [27]

"Natural Fever" Models

Because both endogenous and exogenous pyrogens may, in certain circumstances, act on the cerebral centres to cause endotoxin-induced fever, this widely used experimental model is not entirely satisfactory for studying the pathogenesis of fever in general [27] Not only is it a relatively artificial model involving the injection of toxic foreign substances, but also it is characterised by certain features which appear to have no counterpart in naturally occurring pyrexia—e g , tolerance [8] Hence, studies must be extended to other experimental models, designed to simulate more closely the conditions of naturally occurring pyrexia Two such models have recently been investigated

In 1956 Bennett [7] reported extensive investigation of the fever of experimental pneumococcal peritonitis in rabbits During the febrile phase of the infection he found, in both the peritoneal exudate and the thoracic-duct lymph, a heat-labile substance which appeared to be identical with leucocytic pyrogen Its presence at both sites correlated closely with the animal's fever When defervescence was produced by penicillin therapy, the pyrogen was no longer detected in the exudate Although, in the latter circumstances, leucocytes were still plentiful in the peritoneal exudate, control of the infection apparently removed the stimulus which previously had caused the production of endogenous pyrogen The ability of the blood-stream to rid itself promptly of intravenously injected leucocytic pyrogen had already been established in an earlier study [6] Despite these important and highly suggestive findings, Bennett was unable to demonstrate the fever-producing factor in the blood-stream during the active infection Accordingly he was forced to conclude that the possible causal relationship between the fever and the endogenous pyrogen in the exudate and lymph had not been established

The demonstration of circulating pyrogen in such an experimental model is obviously crucial [6 39 42 46 47] A concerted attempt was therefore made to detect its presence at the height of the febrile phase of the infection When a passive-transfer method was used, in which considerably larger volumes of serum were employed than had been tested by Bennett, a pyrogen similar to that noted in the pneumococcal exudate and lymph was found to be present in the blood-stream [28] The transferable factor in the circulation was also shown to act directly on the thermoregulatory centres [28] Since the endogenous pyrogen in acute granulocytic exudates has been shown to come from polymorphonuclear leucocytes,[26] it now appears to be established beyond reasonable doubt that the fever of pneumococcal peritonitis in rabbits is caused by a circulating endogenous pyrogen produced by the polymorphonuclear leucocytes in the peritoneal exudate and carried to the blood-stream via lymphatic channels emptying into the thoracic duct.[25]

Similar results were obtained with a second experimental model—i e., one involving acute streptococcal cellulitis During the febrile phase of this infection also, an apparently identical endogenous pyrogen has been demonstrated in the blood-stream.[28]

In spite of the evidence provided by these latest experiments, the question may still be raised whether bacterial pyrogens do not play at least a secondary role in the production of pyrexia caused by experimental infections In pneumococcal peritonitis this possibility seems highly unlikely for the following reasons

(1) No bacterial pyrogen has ever been detected in pneumococcal cultures [7]

(2) The pyrogen detected by Bennett in the peritoneal exudate and thoracic-duct lymph was completely inactivated by being heated at 90°C for 30 minutes, did not produce tolerance when repeatedly injected, and was equally active in tolerant and normal recipients [7] In short, no heat-stable component compatible with a bacterial pyrogen was detected in either the exudate or the lymph.

(3) The factor found in the blood-stream was unlike bacterial pyrogen in that (*a*) its activity was the same in normal and tolerant recipients, and (*b*) its pyrogenicity was due to a direct effect on the thermoregulatory centres of the brain.[28]

(4) Relatively prolonged pneumococcal infections (6–9 days) did not induce tolerance to pyrogen,[4] thus virtually eliminating the possibility that a circulating bacterial pyrogen is involved in the pathogenesis of pneumococcal fever

The fact that bacterial endotoxins are active in minute quantities when injected intrathecally [25] suggests that pyrogenic products of the invading pneumococci might gain access to the subarachnoid space and thus contribute to the fever This possibility also appears to be excluded, since bacterial pyrogen was not detected in pneumococcal cultures or in the peritoneal exudate, the thoracic-duct lymph, or the blood-stream,[26 30] it is inconceivable that it could be present in the spinal fluid

In experimental streptococcal cellulitis the situation is complicated by the fact that a bacterial pyrogen can be extracted from β-hæmolytic streptococcal cells [44] However, the endotoxic activity of streptococcal extracts is relatively low,[44] and in this infection the organisms do not invade the blood-stream [28] Here again the circulating pyrogen which appears to cause the fever produces a more rapid febrile response than do bacterial pyrogens Furthermore, unlike bacterial pyrogen, it is uninfluenced by tolerance and acts directly on the central nervous system via the circulation [25]

Even in experimental infections caused by *Escherichia coli*, which is known to possess a powerful pyrogenic endotoxin, there is at present no evidence that the endotoxin is directly involved in the production of fever On the contrary, *Esch coli* infections of 7 or 8 days' duration, like pneumococcal infections, do not produce tolerance to bacterial pyrogens [4] Were the endotoxin to reach the spinal fluid in extracranial *Esch coli* infections, it would still have to traverse the blood-stream In so doing it would certainly be expected to cause some degree of pyrogen tolerance

Thus the conclusion appears justified that the fever of most, if not all, acute bacterial infections which give rise to predominantly granulocytic exudates and do not directly involve the central nervous system are caused by a common factor—i e., a circulating endogenous pyrogen derived from polymorphonuclear leucocytes and analogous to the bloodborne substance found in the sera of rabbits with pneumococcal peritonitis and streptococcal cellulitis [28]

The further possibility that similar circulating endogenous pyrogens, derived from leucocytes or other inflammatory cells, may cause an even wider variety of pyrexia is suggested by the fact that inflammation is common to many pyrexial states, including those resulting from viral infections, vascular lesions, hypersensitivity reactions, and neoplastic diseases [46] Pertinent to this more general hypothesis is the recent observation of Atkins [2] that the febrile response to intravenous injection of influenzal virus is directly related to the presence of a circulating endogenous pyrogen which is indistinguishable from leucocytic pyrogen Whether this newly identified factor is derived from polymorphonuclear leucocytes or from some other cellular source remains to be determined Equally important is Atkins' demonstration (personal communication) of a similar substance in the blood-stream of animals with fever induced by tuberculin hypersensitivity [43] Both these findings, together with those already mentioned relating to pneumococcal and streptococcal infections,[28] support the general theory that endogenous pyrogens derived from inflammatory exudates play a central role in the pathogenesis of many forms of fever

Studies in man [17 20 42] further support this concept Of particular significance is the fact that human serum and plasma have been shown to inactivate bacterial endotoxin [20 22 23‡] This inactivation may be related to the release of phosphorus from the endotoxin molecule [40] When, however, endotoxin is added to human whole blood or to plasma containing leucocytes, incubation for 3 hours results in the formation of a pyrogenic substance which apparently possesses all the biological properties of endogenous pyrogen [42] Since leucocytes are necessary in the system for production of the pyrogen,[17] and since its properties are indistinguishable from those of leucocytic pyrogen,[42] the inference may be drawn that the pyrogen is produced by the leucocytes A difference from the observations made with rabbit leucocytes [26] is that easily demonstrable amounts of the human endogenous pyrogen have been obtained only when the leucocytes have been exposed to the injurious action of endotoxin [39] This difference, however, may be merely quantitative

---

‡ Endotoxin is also inactivated by rabbit serum when incubated at 37 C for more than a few hours [16]

The term “ endogenous pyrogen ” used in this and previous reports [1 2 26–28 46 47] refers to fever-producing substances which are apparently derived from sources within the body Clearly, leucocytic pyrogen [26 42] fits this definition, as do the pyrogenic factors contained in the blood-streams of rabbits with pyrexia caused either by injections of typhoid vaccine [1 2] § or by active pneumococcal and streptococcal infections [28] Unfortunately the same term has been applied by Grant and Whalen [21] to the pyrogenic factor which results from the interaction of bacterial pyrogens and serum Although its use to designate the pyrogen-serum product is justifiable on the grounds that the interaction may occur in the circulation, the resulting pyrogenic factor has been shown to form rapidly in vitro [16] and obviously involves a component which was originally exogenous For these reasons, to avoid confusion, it appears preferable to call the bacterial pyrogen-serum substance by another name The pyrogenic tissue polysaccharides of Landy and Shear [30] also qualify by definition as “ endogenous ”, but they were obtained only by relatively drastic procedures of chemical extraction [30] As emphasised by Landy and Shear, the extracted polysaccharides appear to be active “ only when they are released from their native state of firm combination with other cellular components ”,[30] and there is no evidence that they act directly as pyrogens in the intact host, even under conditions of disease

The endogenous pyrogens, as here defined, are biologically indistinguishable from leucocytic pyrogen (see table) Indeed there are numerous reasons, already reviewed, for believing that the circulating endogenous factor which appears to cause the fever of acute bacterial infections,[28] and that present in the blood during endotoxin-induced fever,[1 2] are both derived from polymorphonuclear leucocytes [26] All attempts to demonstrate similar endogenous pyrogens in saline extracts of other body cells have so far failed [5 9] It is still possible, however, that cells other than granulocytes can produce endogenous pyrogen If these cells could be identified, the fever seen in agranulocytosis and in diseases in which polymorphonuclear leucocytes do not appear to play a prominent role—e g , granulomata and viral infections—might be more readily explained On the other hand, it is not inconceivable that, even in these situations, enough leucocytes are affected in the vast extravascular granulocytic stores of the body [31] to explain the release of endogenous pyrogen Further experimental studies are needed to clarify these points

Chemistry

Since it is evident that leucocytic pyrogen is at least one of the endogenous factors directly responsible for fever, its chemical identity is of great interest Besides being inactivated when heated to 90°C for 30 minutes (at pH 7 2), leucocytic pyrogen is known to be non-dialysable through ‘ Cellophane ’ It has also been reported to be resistant to the actions of trypsin, chymotrypsin, and ribonuclease, and to be unaffected by pH changes ranging from 2 0 to 10 5 Significant pyrogenicity has been demonstrated in preparations containing 0 76 mg of protein and 0 054 mg of polysaccharide [10] Clearly, additional chemical data are needed, and studies designed to procure them are in progress

Summary

There is now strong experimental evidence that endogenous pyrogen derived from polymorphonuclear leucocytes in inflammatory exudates plays a central role in the pathogenesis of many kinds of fever Leucocytes in granulocytic exudates release the endogenous pyrogen into the surrounding medium while still functionally active.

During the febrile phase of experimental pneumococcal peritonitis the pyrogen has been found not only in the peritoneal exudate and the thoracic-duct lymph but also in the blood-stream

An endogenous pyrogen indistinguishable from leucocytic pyrogen has likewise been detected in the sera of rabbits with pyrexia resulting from acute streptococcal cellulitis, from tuberculin hypersensitivity, and from the intravenous injection of typhoid vaccine and of influenzal virus

This recently identified circulating factor acts directly on the thermoregulatory centres of the brain

Its biological properties differ distinctly from those of bacterial pyrogens, pyrexin, and the pyrogenic polysaccharides which can be chemically extracted from normal tissues None of the latter appears to be the direct cause of the fever seen in extracranial bacterial infections

Despite the progress achieved in elucidating the pathogenesis of fever, two major problems remain unsolved (1) the chemical identity of leucocytic pyrogen, and (2) the possibility that cells other than polymorphonuclear leucocytes may be able to elaborate a similar, if not identical, fever-producing factor

§ Endogenous pyrogen is easily demonstrable in the sera of such animals 2 hours after inoculation of the vaccine, at which time the bacterial pyrogen contained in the originally injected vaccine is no longer detectable in the circulation [2]

GROSS DIGITAL CLUBBING AND EXOPHTHALMIC OPHTHALMOPLEGIA IN THYROID DISORDERS

A G Freeman
M A , M D Cantab , M R C P
SENIOR MEDICAL REGISTRAR, BRISTOL ROYAL INFIRMARY AND BRISTOL EYE HOSPITAL, TUTOR IN MEDICINE IN THE UNIVERSITY OF BRISTOL

It is a sobering thought that the pathogenesis of such a common and easily recognisable physical sign as clubbing of the fingers should still not be fully understood As early as the 5th century B C , curving of the finger nails in a woman with an empyema was recorded by Hippocrates Yet the reason why digital clubbing occurs remains a matter of conjecture and controversy

Clubbing of the fingers and hypertrophic pulmonary osteoarthropathy are now generally ascribed either to peripheral anoxia or to a disturbance of endocrine function rather than to the "toxins" of earlier workers (*Lancet* 1955) Nevertheless very few textbooks on clinical medicine or on endocrinology mention the association of finger clubbing with disorders of the endocrine glands For example, although there are some isolated references to the fact that acropachy may, on rare occasions, occur in postoperative myxœdema, far greater emphasis is laid on the fact that the nails usually become atrophic and unduly brittle in this condition

Digital Clubbing, Exophthalmic Ophthalmoplegia, and Hypothyroidism

Thomas (1933) reported a man, aged 22, who first observed curving of his finger nails about eight months after partial thyroidectomy for exophthalmic goitre Sixteen months later he was mildly myxœdematous and had œdema of the eyelids There is no indication in the case-report whether the exophthalmos had progressed or diplopia had developed Extreme clubbing of the fingers and enlargement of the hands and wrists were present The toenails were normal Radiography revealed tufting of the terminal phalanges and much subperiosteal formation of new bone, the sella turcica was normal

Cushing (1937) described a further case A negro, aged 37, first noticed that the tips of his fingers were becoming swollen eight months after subtotal thyroidectomy He had severe digital clubbing, and radiography showed generalised hypertrophic pulmonary osteoarthropathy affecting his long bones and metacarpals His basal metabolic rate was −24% compared with +55% before operation As in the previous case, nothing is said about whether ophthalmoplegia had complicated the pre-existing exophthalmos

Rynearson and Sacasa (1941) reported a man, aged 43, who became hypothyroid and developed clubbing of his fingers six weeks after partial thyroidectomy for thyrotoxicosis Two years after the operation his exophthalmos had increased and he had brawny irregular non-pitting œdema of the lower half of his legs His basal metabolic rate was −13%, and radiography showed subperiosteal thickening of his phalanges

Greene (1951) described a man, aged 74, with hypothyroidism, malignant exophthalmos, and gross clubbing of the fingers and toes, who at the age of 56 in 1932 had an enlarged thyroid gland, exophthalmos, an enlarged heart, and chronic bronchitis He had no digital tremor or tachycardia After treatment with potassium iodide the goitre disappeared At this time his fingers were clubbed but, according to his relations, this only became severe seventeen years later, when progressive exophthalmos appeared He also had pretibial thickening of his skin Radiography of his chest showed emphysema, a bronchogram was normal Radiography of his skull showed no abnormality, radiography of his hands and feet revealed the formation of new bone along the shafts of his phalanges and metacarpals

This man died in 1951 A necropsy was done by Dr A B Bratton, and I am indebted to Dr Greene for sending me full details of the hitherto unpublished necropsy findings In summary, there were considerable hypertrophy of the left ventricle, œdema of the lungs, and emphysema A cystic adenoma was present in the left lobe of the thyroid gland, and microscopy revealed lymphocytic infiltration, massive fibrosis, and scanty colloid in the small residual nodules of thyroid epithelium The suprarenal glands had abundant lipoid in the cortex and considerable lymphocytic infiltration of the medulla There was an eosinophil chromophil adenoma of the anterior lobe of the pituitary gland

Inch and Rolland (1953) reported 2 cases in which pretibial myxœdema and gross digital clubbing were associated with exophthalmic ophthalmoplegia One case was in a woman who developed an exophthalmic goitre at the age of 36 Within nine months of partial thyroidectomy she had signs of hypothyroidism, ophthalmoplegia, pretibial myxœdema, and finger clubbing The other case was in a man who became thyrotoxic at the age of 20 After X-irradiation of the thyroid gland he became euthyroid and developed exophthalmos with mild ophthalmoplegia He was first seen by Inch and Rolland nineteen years later with considerable exophthalmos, some ophthalmoplegia, pretibial myxœdema, and gross finger clubbing The patient did not know when the clubbing had begun to appear

Analysis of these 6 case-reports reveals that the clinical features common to all were digital clubbing and exophthalmos 5 patients were hypothyroid, and 1 was euthyroid This hypothyroid or euthyroid state followed partial thyroidectomy or X-irradiation of the thyroid gland for thyrotoxicosis in 5 patients In 1 case myxœdema was first noticed about seventeen years after the goitre had disappeared after treatment with potassium iodide

Exophthalmic ophthalmoplegia was present in 4 cases, whereas in 2 (Thomas 1933, Cushing 1937) it is not said whether the pre-existing exophthalmos had increased or diplopia had developed In 4 patients digital clubbing came on between six weeks and nine months after either partial thyroidectomy or X-irradiation of the thyroid gland and closely followed the symptoms of hypothyroidism In 1 case the patient did not know when the clubbing had first appeared In the other case, although the clubbing had appeared before the goitre had been treated with potassium iodide, it had only become severe seventeen years later, when hypothyroid symptoms and malignant exophthalmos had developed Pretibial myxœdema was observed in 3 of the 6 cases

A further case is now reported

Case-reports

Case 1 —An engine driver, aged 56, was referred to the Bristol Eye Hospital in October, 1957, with three months' history of increasing prominence of his eyes For three weeks

he had had progressive swelling of his left upper eyelid and watering of the eye During the preceding seven days he had had pain in his left eye and photophobia and could not close his eye completely In 1929, at the age of 28, subtotal thyroidectomy followed by X-irradiation of the thyroid gland were undertaken for thyrotoxicosis of some eleven months' duration The hospital records state that after this treatment the exophthalmos regressed somewhat and the patient regained his previous weight For four months before be was seen at the Bristol Eye Hospital he had felt tired and been unduly sensitive to cold, and his skin had become rough and dry and his voice a little husky, and he was constipated There was no apparent impairment of memory or of power to concentrate For about twenty years up to the time of admission he had been driving a main-line express train

On examination his speech was a little slow and slurred and his voice low-pitched He had coarse features, a dry scaly skin, dry hair, and a puffy face No circumscribed or pretibial myxœdema was found Gross clubbing of his fingers and toes was present (fig 1) There was neither pain nor swelling of his ankles, feet, or wrists Marked bilateral exophthalmos (exophthalmometer right eye 29 mm , left eye 28 mm *) was present Œdema and inflammation of his periorbital tissues and the infracorneal conjunctiva were severe His left eye was lagophthalmic, with eversion of the lower lid, exposing œdematous conjunctiva and producing epiphora (fig 2) He had no diplopia, but he had difficulty in looking upwards His visual acuity was right 6/9, left 6/18, his ocular fundi and visual fields were normal His cardiovascular system, chest, and abdomen revealed no abnormal physical signs

Investigations and follow-up examination—During his stay in hospital the patient's temperature was 96–98°F and pulse-rate 60–70 Blood-counts and liver-function tests were normal, his plasma-cholesterol level was 280 mg per 100 ml

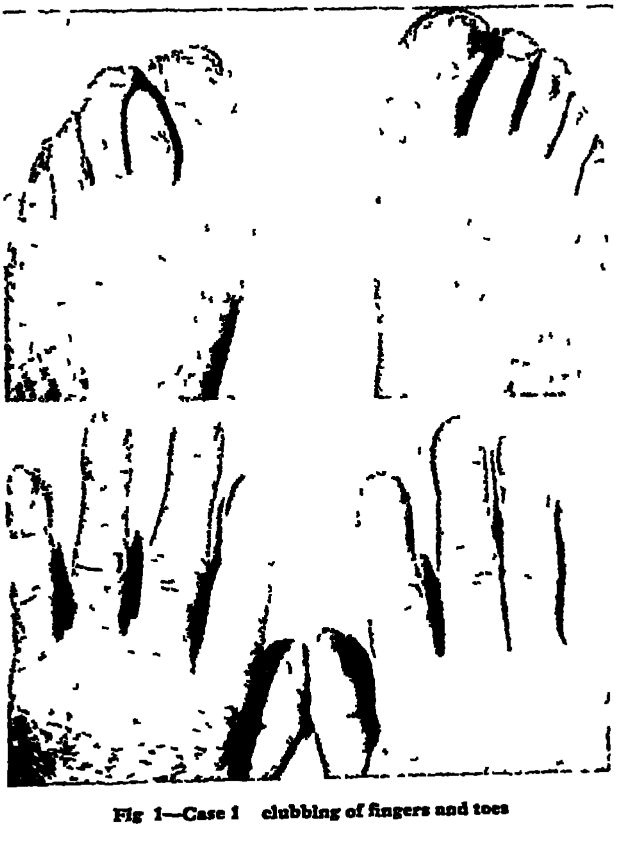

Fig 1—Case 1 clubbing of fingers and toes

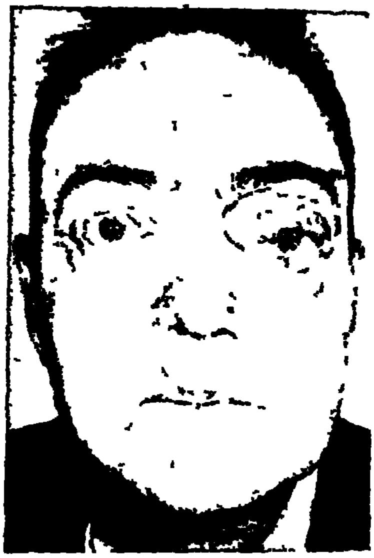

Fig 2—Case 1 malignant exophthalmos Left lateral and central and right lateral tarsorrhaphies had been done as emergency measure

Electrocardiography revealed flattening of the T waves in all leads Radiography of his chest showed fibrotic changes in the anterior segment of the right upper lobe and bilateral basal emphysema Bronchography showed all the main segmental bronchi in both lungs and no evidence of bronchiectasis Radiography of his skull, hands, and long bones was normal, but there was periosteal new bone on the medial aspects of both first metatarsals (Dr J H Middlemiss) Radioactive-iodine estimations showed that at four hours the total uptake was as low as 9% of the dose, and at forty-eight hours the protein-bound ^{131}I level in the plasma was 0 13% of the dose per litre, the values obtained being consistent with the clinical diagnosis of myxœdema A left central and lateral tarsorrhaphy and a right lateral tarsorrhaphy were done as an emergency measure, and a course of X-irradiation to the orbits has now been given

Comment—There was no history or clinical evidence of pulmonary, cardiac, hepatic, or intestinal disease in this patient and no family history of clubbing of the fingers Although the plain radiographs of his chest showed fibrotic changes in the anterior segment of the right upper lobe, bronchography showed no bronchiectasis The patient and his wife both thought that the clubbing of his fingers had been present for only three or four months In this patient, therefore, there was a definite association between the onset of digital clubbing, exophthalmic ophthalmoplegia, and clinical manifestations of hypothyroidism

Digital Clubbing, Exophthalmic *Ophthalmoplegia*, and Thyrotoxicosis

Although it is well known that trophic disturbances leading to koilonychia may develop in thyrotoxicosis, Branwood (1949) stated that clubbing of the fingers is not seen in this condition I have been unable to find any reference or case-report similar to case 2 (see below) describing the clinical triad of gross digital clubbing, exophthalmic ophthalmoplegia, and untreated active thyrotoxicosis

Case 2.—A warehouseman, aged 54, was admitted to the Bristol Eye Hospital in October, 1956, with six months' history of nervousness, irritability, palpitations, and increasing prominence of his eyes In spite of having a good appetite he had lost almost 2 stones in weight. During the previous four weeks he had had puffy eyelids Pain in his eyes and photophobia had been present for three days

On examination he was nervous and agitated His skin was warm and moist, and a fine tremor of his fingers was present His resting pulse-rate was 130, with normal rhythm His blood-pressure was 180/95 mm Hg His thyroid gland was easily palpable and uniformly enlarged A loud systolic bruit was audible over his neck Bilateral proptosis (exophthalmo-

---

* Since there appears to be a wide range of measurements made with a Hertel exophthalmometer in healthy people, the degree of exophthalmos is not given For example, Brain and Turnbull (1938) state that the average normal reading is 12 5 mm , whereas Rundle and Wilson (1945) report the average values in controls measured by the same instrument as 16 9±1 8 mm , with the upper limit of normal as high as 23 0 mm

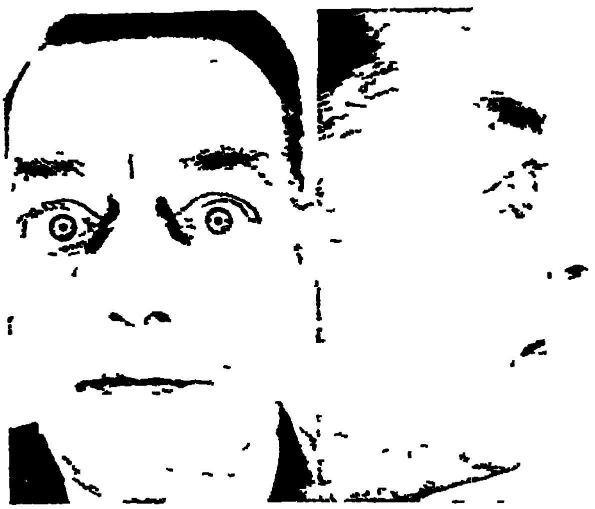

Fig 3—Case 2 malignant exophthalmos.

meter right eye 25 mm., left eye 26 mm.*) was present. Lid lag, lid retraction, and widening of the palpebral fissures were evident. His upper and lower eyelids were œdematous and inflamed, and chemosis was present (fig. 3). There was some weakness of elevation and abduction in both eyes, and the patient complained of double vision when attempting to look to the extreme left and right. His visual acuity was right 6/6, left 6/5, his ocular fundi and visual fields were normal. He had no pretibial myxœdema. He also had gross clubbing of his fingers and toes (fig. 4). He had no enlargement of his hands and feet and no pain or swelling of his ankles, feet, or wrists. His face showed no sign of acromegaly. He had some thickening and furrowing of his skin over his forehead. His heart, lungs, and abdomen were normal clinically.

Investigations.—Complete blood-counts, liver-function tests, and radiography of his thoracic inlet, chest, long bones, hands, and feet were all normal. Radiography of his skull showed no intracranial abnormality, and his sella turcica was normal. Radioactive-iodine measurements showed that the total uptake was 82% of the dose, at four hours, and at 48 hours the protein-bound ^{131}I level in the plasma was 1·35±0·08% of the dose per litre, values consistent with thyrotoxicosis.

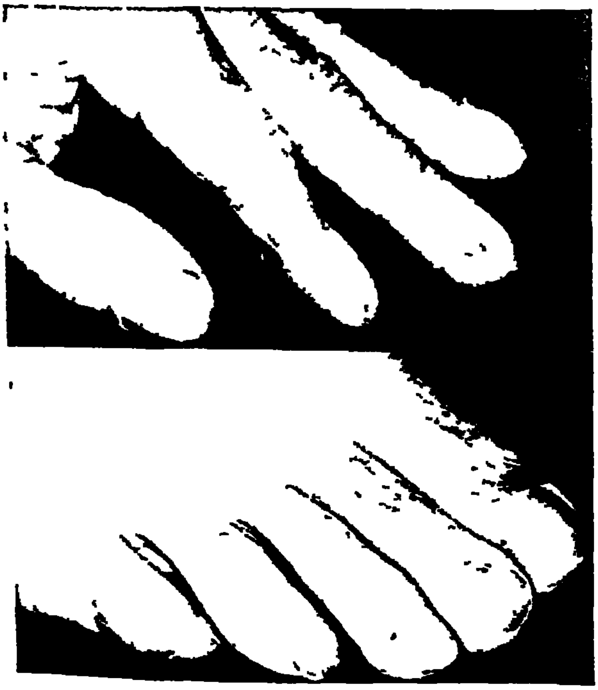

Fig 4—Case 2 clubbing of fingers and toes.

Progress.—Bilateral lateral tarsorrhaphies were done and the patient was transferred to the Bristol General Hospital for radioactive-iodine therapy. He became euthyroid and in twelve months there was definite improvement in his exophthalmos and ophthalmoplegia. His extreme digital clubbing has remained unchanged, and no signs of circumscribed myxœdema have appeared.

Comment.—In this patient there was no family history of digital clubbing and no evidence of cardiac, pulmonary, hepatic, or intestinal disease. Although the skin over his forehead appeared a little thickened and furrowed, he had no prominent skin folds on his cheeks, exaggeration of the normal nasolabial folds, or enlargement of his extremities, all of which are such characteristic features of pachydermoperiostosis (idiopathic osteoarthropathy) (Angel 1957). The patient had first noticed curving of his finger-nails about two or three months before he was seen at the Bristol Eye Hospital.

It therefore appears that the development of digital clubbing closely followed the onset of symptoms and signs of a toxic goitre and progressive exophthalmos. When the patient was first seen in October, 1956—six months after the onset of his thyrotoxic symptoms—gross digital clubbing, exophthalmic ophthalmoplegia, and signs of active thyrotoxicosis were present.

Discussion

Pretibial myxœdema—first described by a Bristol physician (Watson-Williams 1895)—and its association with exophthalmic ophthalmoplegia are now well recognised. The complete clinical triad with gross digital clubbing is evidently rare but apparently not so rare as the paucity of published reports suggests.

Analysis of the published case-reports shows that a definite association between the onset of acropachy, exophthalmic ophthalmoplegia, pretibial myxœdema, and hypothyroidism existed in 2 men (Rynearson and Sacasa 1941, Greene 1951) and 1 woman (Inch and Rolland 1953). In a further 3 cases reviewed the association between acropachy and exophthalmic ophthalmoplegia is not proved, because insufficient data about the time of onset of digital clubbing and the presence of malignant (as opposed to benign) exophthalmos is recorded. Levitt (1953) wrote that he had seen 8 such patients, but he gave no further clinical details.

In the present case 1 the development of severe digital clubbing and progressive exophthalmos with ophthalmoplegia closely followed the onset of classical symptoms and signs of myxœdema. In case 2 gross clubbing of the fingers and toes and exophthalmic ophthalmoplegia developed in a patient with a toxic goitre. No other case of severe digital clubbing in untreated active thyrotoxicosis seems to have been published. There were no signs of pretibial myxœdema in either of these 2 cases.

Clinical Manifestations of Pituitary Dysfunction

Exophthalmic ophthalmoplegia.—The concept expressed by many workers that exophthalmic ophthalmoplegia is due to overproduction of the thyroid-stimulating hormone (T.S.H.) of the anterior lobe of the pituitary gland has been challenged by Gilliland and Strudwick (1956). Using a new method of clinical assay of T.S.H. in the serum which would not be affected by the presence of excess thyroid hormone, these workers found a high level of T S H in most patients with spontaneous myxœdema and in cretins comparable with the raised level also obtained in 8 patients with thyrotoxicosis and severe eye signs Further, the T S H levels in 3 patients with exophthalmic ophthalmoplegia without thyrotoxicosis did not differ from those found in healthy controls Gilliland and Strudwick therefore conclude that oversecretion of T S H *is not the sole cause of exophthalmos*

The supposed existence of an "exophthalmos-producing" hormone, possibly also of pituitary origin, as a separate entity from T S H is supported by the findings of Querido and Lameyer (1956) In 18 thyrotoxic patients *there was no significant difference between the levels of* T S H in the serum of 9 patients without serious eye signs and in that of 7 with serious eye signs Further, the circulating T S H levels were repeatedly low in 1 euthyroid patient who developed malignant exophthalmos after partial thyroidectomy, and were very high in another with only slight proptosis, pretibial myxœdema, and postoperative hypothyroidism Thus there appears to be no direct correlation between the levels of T S H *in the serum and the presence and degree of* exophthalmos

Digital clubbing —The question now to be considered is whether acropachy can ever be regarded as a clinical manifestation of pituitary dysfunction

Bloom (1948) reported chronic hypertrophic pulmonary osteoarthropathy and gynæcomastia *in a man* with a carcinoma of the bronchus He found metastases in the anterior lobe of the pituitary gland at necropsy and suggested that these had excited the production of anterior-lobe hormones in sufficient quantity to produce the bone changes, digital clubbing, and gynæcomastia which had developed during the course of the disease The regression of digital clubbing which often occurs after lung resection clearly excludes stimulation of the hypophysis as a common cause, and Flavell (1956) has shown that severing the vagus nerve on the same side as the affected lung also completely reverses the signs of osteoarthropathy

On the other hand, Fried (1943) has presented evidence in support of dyspituitarism as an ætiological factor in some cases He described the *development of* chronic hypertrophic pulmonary osteoarthropathy, clubbing of the fingers, and clinical and radiological features of acromegaly in 4 patients with a bronchogenic carcinoma Ellman (1953) and Järvinen and Kumlin (1954) also reported similar clinical findings in 4 patients with the same neoplastic condition Hyperplasia of the eosinophil cells of the anterior lobe of the pituitary gland without any metastatic involvement of the endocrine glands was *found in* all 4 patients on whom postmortem examinations were performed

Levitt (1954) wrote

> "The presence of pulmonary osteo-arthropathy in a patient with severe malignant exophthalmos and localised œdema of the legs support the view that the pituitary gland is closely associated with this phenomenon The associated eosinophil hyperplasia present in the pituitary gland adds further support to the view that the growth factor is very closely allied to the proliferative thyroid hormone"

The hitherto unpublished necropsy findings in the case presented by Greene (1951) merit particular emphasis This male patient, with hypothyroidism, gross digital clubbing, malignant exophthalmos, and pretibial myxœdema, died at the age of 76 Some seventeen years before he was first seen by Dr Greene he had been treated with potassium iodine for an apparently non-toxic goitre, and after this treatment the thyroid enlargement had disappeared Necropsy showed severe thickening of the fingers and toes and formation of new bone along the shafts of the metacarpals Pulmonary congestion was present, but there were no signs of a bronchogenic carcinoma *Massive* fibrosis of the thyroid gland and an eosinophil *chromophil* adenoma of the anterior lobe of the pituitary gland were also found

Conclusions

The role of the pituitary gland in the production of exophthalmic ophthalmoplegia and in the *pathogenesis* of digital clubbing has been studied and reviewed by many workers

The concept of an "exophthalmos-producing" hormone as a separate entity from the thyroid-stimulating hormone of the pituitary gland is now widely held In the light of clinical and necropsy findings the development of acropachy and chronic hypertrophic pulmonary osteoarthropathy in some patients with a bronchogenic carcinoma has been ascribed to a disturbance *of* pituitary function In this connection the necropsy findings are of *particular* interest *in* 2 patients with either *medically* induced or postoperative hypothyroidism associated with malignant exophthalmos, pretibial myxœdema, and gross digital clubbing one patient had an *eosinophil chromophil* adenoma of the pituitary gland, the other had eosinophil hyperplasia of the anterior lobe of the pituitary gland

The association of acropachy and exophthalmic ophthalmoplegia in patients with either postoperative or medically induced myxœdema *is not so rare as might be expected* from the paucity of published reports On the other hand, the development of severe digital clubbing and exophthalmic ophthalmoplegia in untreated active thyrotoxicosis (case 2) does not appear to have been previously described

The fact that gross digital clubbing is now reported in association with exophthalmic ophthalmoplegia in hyperthyroid, as well as in induced euthyroid and hypothyroid states, adds further support to the view that this syndrome, with or without pretibial myxœdema, is a clinical manifestation of pituitary dysfunction

I am indebted to Mr C A Brown and Dr A M G Campbell *for permission to publish the two case-reports*, Dr J L James for helpful criticism and advice, and Mr F A Godman, of the department of photography, University of Bristol, for the photographs

INTRINSIC-FACTOR-INHIBITING SUBSTANCE IN SERUM OF ORALLY TREATED PATIENTS WITH PERNICIOUS ANÆMIA

MICHAEL SCHWARTZ
M.D. Copenhagen
PHYSICIAN AND LECTURER, MEDICAL DEPARTMENT B,
BISPEBJERG HOSPITAL, COPENHAGEN, DENMARK

PERNICIOUS anæmia has been extensively treated with intrinsic factor for more than twenty-five years, especially in the Scandinavian countries Formerly the preparations consisted of more or less crude dried hog gastric pylorus, but in the past five or six years a new type of oral preparation has become very popular purified hog pyloric mucosa plus vitamin B_{12} It has been shown that only 100 mg of hog pyloric mucosa causes substantial absorption of vitamin B_{12} in pernicious anæmia, and such preparations administered initially almost always produce complete remission. But in prolonged treatment with preparations of this type a considerable proportion of the patients relapse, and several have shown myelopathy—even without hæmatological relapse in the peripheral blood. (Blackburn et al. 1955, Meulengracht 1955, Norregaard 1955, Bastrup-Madsen 1957)

The cause of the failure of these newer oral preparations is a block in the intestinal absorption of vitamin B_{12} with hog pyloric mucosa as intrinsic factor, the block is not present when homologous intrinsic factor is administered (Schwartz et al 1957) This intestinal block has been confirmed by several workers (Berlin et al 1957, Killander 1957, Lowenstein et al. 1957, Allgen and Tomenius 1958, Stokes and Pitney 1958) but its cause has not been found so far The block may be due to some sort of sensitisation, two groups found no evidence of immunity in such patients, but they did not state how their investigation was carried out. (Stokes and Pitney 1958, Adams 1958) Recently an antibody to Castle's intrinsic factor was reported by Taylor and Morton (1958) They immunised rabbits with intrinsic-factor preparations from man and from pig pylorus and found in the serum of the treated rabbits a substance inhibiting human and pig intrinsic factor respectively

As part of investigations in this hospital into the cause of the intestinal block in orally treated patients with pernicious anæmia several sera from healthy persons and patients with pernicious anæmia were examined for antibody against intrinsic factor

Methods

The Schilling (urinary excretion) test was used throughout, 0·5 μg ^{60}Co vitamin B_{12} (with 0·1 μC) was administered by mouth, and 2 hours later 1 mg unlabelled vitamin B_{12} intramuscularly ^{60}Co vitamin B_{12} excretion was determined in 24-hour specimens of urine.

The patients all had typical pernicious anæmia with a low (0–7·1%) ^{60}Co vitamin B_{12} excretion when tested without intrinsic factor, and a normal ^{60}Co vitamin B_{12} excretion (in this series 12·2–28·2%) with 100 mg hog pyloric mucosa.

TABLE II—URINARY EXCRETION IN SCHILLING TEST PERFORMED WITHOUT INTRINSIC FACTOR, WITH HOG INTRINSIC FACTOR ALONE, AND WITH HOG INTRINSIC FACTOR MIXED WITH 50 ML. SERUM FROM PATIENTS WITH UNTREATED PERNICIOUS ANÆMIA. FIGURES ARE PERCENTAGES OF ADMINISTERED ^{60}CO VITAMIN B_{12} EXCRETED IN URINE IN 24 HOURS

0	16·0	14·9
0	16·4	13·8
0	14·0	15·1
0	16·4	17·7

Serum from healthy persons and four groups of patients with pernicious anæmia was investigated (1) untreated pernicious anæmia, (2) pernicious anæmia treated for 1–5 years with oral preparations of vitamin B_{12} plus hog pyloric mucosa, (3) pernicious anæmia treated orally with a crude stomach preparation ('Pyloron-Exopyloron'), (4) pernicious anæmia treated by injection. 50 ml of serum was used in all experiments

The test for antibody against intrinsic factor was carried out as follows 100 mg hog pyloric mucosa was mixed with a small amount of water and then with 50 ml. serum at room temperature. Ten minutes later the mixture was given with the test dose of ^{60}Co vitamin B_{12}

Results

The results are shown in tables I–IV.

Serum from healthy persons (table I) and patients with untreated pernicious anæmia (table II) does not contain any intrinsic-factor-inhibiting substance

Sera from 21 patients with pernicious anæmia treated orally for more than a year with preparations of vitamin

B_{12} plus hog pyloric mucosa were investigated (table III) 16 of these sera inhibited the intrinsic-factor activity—in several cases almost completely 13 of these 16 patients were investigated with ^{60}Co vitamin B_{12} and 100 mg hog pyloric mucosa, and all were found to have a blocked intestinal absorption, 3 were not investigated, but in at least 1 of these patients absorption was probably blocked (serum-vitamin-B_{12} 32 µµg per ml after two years' treatment)

Of the 5 patients without intrinsic factor antibody in their serum, 3 were investigated, in 2 blockade was found, and the 3rd had normal vitamin-B_{12} absorption

Serum from 6 patients with pernicious anæmia, treated orally for some time (six months to twenty years) with crude stomach preparations, showed gross inhibitory activity in 3 cases (table IV) The intestinal absorption was investigated in all 6 patients, 1 had a slightly reduced absorption (8 7% excretion with the Schilling test), whereas in the other 5 the absorption was normal

Serum from 2 patients treated by injection showed no intrinsic-factor-inhibiting activity

In some cases the experiments were repeated with the same sera ^{60}Co vitamin B_{12} and hog pyloric mucosa were mixed 10 minutes before the addition of serum The intrinsic-factor-inhibiting activity was found unaltered by this procedure (probably indicating that it is directed against the vitamin B_{12} plus intrinsic factor)

3 sera known to inhibit hog pyloric mucosa activity were tested in the same way, using human fundus mucosa as intrinsic factor In 2 cases there was pronounced inhibiting activity against this homologous intrinsic factor

Discussion

Intrinsic-factor-inhibiting activity in sera from patients with pernicious anæmia treated orally has not previously been reported In order to examine as many sera as possible it was decided not to change the procedure in this investigation Further studies, especially serological, are necessary Possibly this intrinsic-factor-inhibiting substance is analogous with the intrinsic-factor-antibody produced experimentally in rabbits by Taylor and Morton (1958)

It is reasonable to assume that it is produced by the oral treatment, and it may partly explain why so many patients with pernicious anæmia, treated orally with vitamin B_{12} plus hog pyloric mucosa, develop a more or less blocked intestinal absorption of vitamin B_{12} But this intrinsic-factor-inhibiting activity cannot alone explain the intestinal blockade Patients treated with crude pig stomach preparations can have a quite normal intestinal vitamin-B_{12} absorption with hog pyloric mucosa and considerable intrinsic-factor-inhibiting activity in their serum Furthermore the inhibiting activity was found to operate against human intrinsic factor

Summary

Intrinsic-factor-inhibiting activity was found in a considerable proportion of sera from patients with pernicious anæmia treated orally Serum from healthy persons and patients with untreated pernicious anæmia contained no such activity

As intestinal absorption of vitamin B_{12} proved to be normal in some cases with inhibiting activity in the serum, and as the intrinsic-factor-inhibiting activity was shown to operate also against human intrinsic factor, such activity is probably not the sole cause of the intestinal blockade following long-continued oral treatment of pernicious anæmia

I wish to thank Medicinalco, Ltd , of Copenhagen, for liberal supplies of intrinsic factor This study was supported by the Statens Videnskabsfond, University of Copenhagen

FACIAL SINUSES SECONDARY TO PULMONARY TUBERCULOSIS

W C MELLOR
F D S R C S

C R STOCKDALE
L D S Manc

From the Department of Oral and Dental Diseases, Crumpsall Hospital, Manchester, 8

IN three cases referred to us for the treatment of discharging sinuses on the face the lesions were found to be secondary to pulmonary tuberculosis We know of only one such case (Oppenheim et al 1950) previously reported

Case-reports

Case 1—A man, aged 33, had had an "abscess" in the left upper premolar region, 8 months previously This was incised externally, but continued to discharge through a sinus He had recently noted dyspnœa and a cough

On the left cheek, about 1½ in distal to the angle of the mouth, was a depressed scar surrounding a sinus from which watery straw-coloured pus was discharging Below the outer canthus of the left eye was a healed sinus with surrounding scar tissue, the centre of which was fluctuant (fig 1) The dental condition was poor A thick fibrous band was palpable in the buccal sulcus running from the alveolus in the $\underline{|45}$ region to the cheek Roots of the $\underline{|45}$ teeth were present,

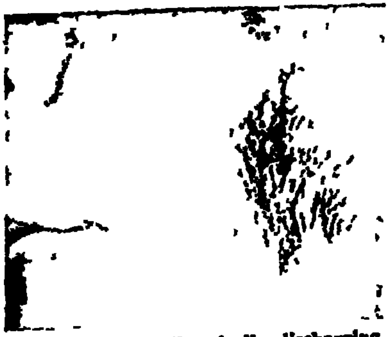

Fig 1—Case 1 Chronically discharging facial sinus

and radiographs showed rarefaction round the apices. *Staphylococcus albus* and *aureus*, sensitive to penicillin, were cultured from pus from the sinus, no actinomyces were seen. Intramuscular penicillin was given. All his teeth were removed, under a general anaesthetic, and the sinus on the cheek was explored. It appeared to end in the alveolar bone in the /45 region. No healing of the sinus took place, and cultures a week later produced *Staph albus*, sensitive only to chloramphenicol. This antibiotic was now given in place of penicillin.

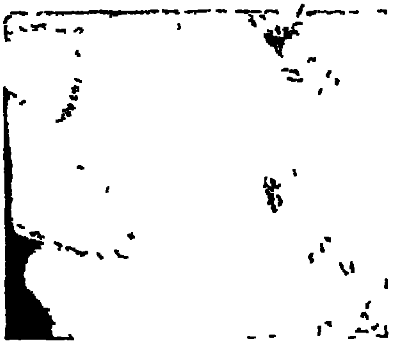

Fig 2—Case 1 Sinuses healed after systemic treatment for pulmonary tuberculosis

The temperature charts showed a "swinging" pattern like that seen in a tuberculous infection. Radiographs of the chest showed effusion at the base of both lungs and granular mottling throughout both lung fields, with some cavitation at the apices, suggestive of pulmonary tuberculosis. The sputum contained acid- and alcohol-fast bacilli, and pus from the sinus yielded tubercle bacilli, in pure culture.

When the patient was seen 12 months later, after medical treatment, the sinuses had healed and the scarring was much reduced (fig 2).

Case 2.—A man, aged 22, was referred for a submandibular swelling. 4 weeks previously, the tooth had been extracted because of an acute alveolar abscess. The submandibular swelling had then increased in size, and his doctor had incised and drained it, since when it had been discharging.

Midway along the left mandible and below its lower border was a fluctuant area, about 2 cm in diameter, surrounded by an area of fibrous tissue. The overlying skin was hyperæmic, and there were signs of a partially healed sinus. There was a second smaller swelling below the main area, and slight left submandibular adenitis. No intra-oral abnormalities were noted, the /7 socket was healing normally.

The sinus in the left submandibular region was reopened, and produced watery straw-coloured pus. Radiographs of the left mandible showed no lesion. Cultures of the discharge grew coagulase-negative staphylococci sensitive to penicillin.

Penicillin was given, but after a week there was little change in the condition. Accordingly, under general anæsthesia the sinus and the surrounding scar tissue was excised. A mass of granulation tissue was found with finger-like extensions, this was removed and the wound closed in layers. 14 days after operation a watery yellow discharge was coming from the two suture holes. At this stage tuberculosis was diagnosed in case 1, and in view of the similarity of his lesions, the second patient was also referred for a chest radiograph, which revealed a tuberculous appearance in the left lung. With appropriate medical treatment, the sinuses rapidly healed.

Fig 3—Case 3 Chronically discharging sinus in the left submental region

Case 3.—A man, aged 33, had a fracture of the right mandible involving an unerupted premolar tooth. Splints were applied by means of peralveolar and circumferential wires, fixation was achieved and maintained for 6 weeks, and union took place.

5 months later he returned with a discharging sinus in the left submental region (fig 3). It had begun a week earlier as a painless swelling, which had increased in size, burst, and drained extraorally, with persistent discharge.

A swelling about $^3/_4$ in. in diameter was present in the left submental region. Pressure produced watery pus. The sinus coincided with the puncture hole that had been made in the skin to pass the circumferential wire. No intra-oral abnormalities were noted, and radiographs of the left mandible revealed no lesion.

Again the striking similarity of the lesion to that in case 1 prompted us to order an immediate chest radiograph, and this showed infiltration of the right and left upper and mid zones of the lungs. Bilateral cavitation was evident, and the sputum contained acid- and alcohol-fast bacilli. With treatment of his pulmonary tuberculosis, the submental lesion healed, and after 17 weeks there was only a scar (fig 4).

Discussion

Tuberculous ulceration of the mouth may be primary or secondary. Secondary infection is more common, Cameron (1939) quoted an incidence of 1 case of ulceration in 1892 cases of pulmonary tuberculosis. The small numbers of cases suggest that the tissues of the oral cavity offer resistance to tuberculous infection. The explanation of this might be (1) resistance of epithelium to the invading organisms, (2) protective and germicidal action of saliva (3) rich blood-supply of the region, (4) constant movements of the tongue and cheeks, preventing long contact with the bacilli, or (5) antagonistic action of various bacteria to one another.

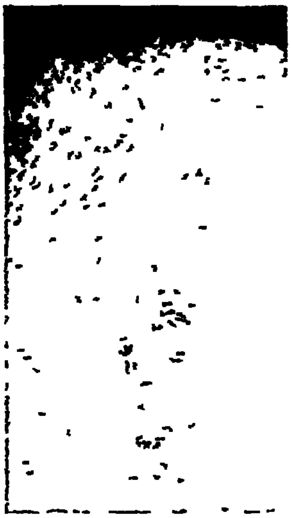

Fig 4—Case 3 Sinus healed after systemic treatment for pulmonary tuberculosis

Chapotel (1930) wrote that only 50 cases of tuberculosis of the mandible had been reported up to 1922, and it was always associated with tuberculosis elsewhere. He suggested the following pathways by which infection reached the jaws (1) from a tuberculous lesion of the gingivæ, (2) from infected sputum through the gingival tissues during tooth eruption, and (3) hæmatogenous spread.

Port and Euler (1951) thought that spread of tubercle bacilli to the jaw is more likely to be hæmatogenous than via a carious tooth, they cited the incidence of tuberculous infection of the zygomatic process, despite its relative great distance from the teeth.

Meng (1940) described 14 mandibular bone lesions, in 10 of which the chest was studied radiographically and revealed pulmonary tuberculosis.

60% of Chapotel's patients were under the age of 15, whereas Meng's patients varied in age from 4 to 48, 11 being between 10 and 30. Pilcher and Trauner's (1948) findings were similar to Chapotel's.

Partsch (1904), Darlington and Salman (1937), Gomouec (1939), and Brodsky (1942) demonstrated tubercle bacilli in the periapical tissues of a tooth Infection of sockets following extractions has occurred in patients with pulmonary tuberculosis (Burman and Jonsson 1935)

Oppenheim et al (1950) reported one case of pulmonary tuberculosis where a fistula arose from the buccal mucosa through the skin of the cheek

There is a similarity in our three cases The first two patients complained of a " dental abscess ", and the third a swelling similar to a dental infection, as the initial symptom None had pain The discharging sinuses had the chronicity and lack of inflammatory symptoms of a tuberculous " cold abscess ". The sinuses and discharge were strikingly similar, together with an abnormal amount of fibrous tissue, especially in the first two cases

It can be assumed that the lesions of the jaws were secondary to those in the lungs, but the route of infection is debatable In cases 1 and 2 retained roots and carious teeth were present, allowing ingress of bacilli In case 1 the tubercle bacilli in the sputum could have entered via the retained roots or through the blood-stream, and secondarily infecting a non-specific granuloma In case 2 infection could have followed the extraction, if it was not already present In case 3, we think, tubercle bacilli from the sputum tracked down the circumferential wire to the soft tissues From the removal of the wire 5 months elapsed before the lesion appeared in the left submental region

In our cases infection spread by the sputum seems more likely than infection via the blood The staphylococci in the discharge, presumably arising from infected teeth, initiated an abscess and a sinus which favoured the superimposition of tuberculous infection

Three constant factors in our cases are

They had active pulmonary tuberculosis

Pathways from mucous membrane to skin existed and opened up a route of infection by sputum

A typical and easily recognisable facial lesion developed

The clinical picture suggests that the deeper dermal layers have relatively little resistance to tuberculous infection, for mucous membrane, bone, periosteum, overlying soft tissues and skin were subjected to the same infection but were unaffected Except the dermal structures, all healed normally

Summary and Conclusion

Three cases are reported in which investigation of sinuses associated with jaws led to the diagnosis of unsuspected pulmonary tuberculosis

In the treatment of dental conditions care should be taken to prevent external sinus formation, and to maintain a healthy mouth during treatment, even if this necessitates extensive conservative treatment of the teeth and gums

We are indebted to Dr Henry B Slater, chest physician of Ashton-under-Lyne, for advice and progress reports on cases 1 and 3 We also thank Miss J L Perry, of Crumpsall Hospital, Manchester, for the photographs

ANTIBIOTIC-RESISTANT STAPHYLOCOCCAL OUTBREAKS IN A MEDICAL AND A SURGICAL WARD

MARY BARBER
M D Lond
READER IN CLINICAL BACTERIOLOGY

A A C DUTTON
M A , B M Oxon
ASSISTANT LECTURER IN BACTERIOLOGY

POSTGRADUATE MEDICAL SCHOOL OF LONDON

OUTBREAKS of staphylococcal infection in hospital wards are now common The two reported here are of special interest because in both cases the origin was traced to an infected patient admitted to the ward, and the strains isolated were resistant to erythromycin as well as to penicillin, streptomycin, and tetracycline

The first outbreak was in a male medical ward Although the epidemic strain was scattered through the ward it was responsible for no severe infection and was eliminated without closure of the ward

The second outbreak, which was in a male surgical ward, was responsible for 11 infections, many of which were severe, and was controlled only by closing and disinfecting the ward

Bacteriological Methods

Staphylococci from infections were isolated in the routine laboratory on blood-agar plates, and all coagulase-positive strains were kept for further investigation Nutrient-agar plates containing phenolphthalein phosphate (Barber and Kuper 1951) were used for isolating staphylococci from nasal swabs, bedding, curtains, and the air of the wards Phosphatase-positive colonies were tested for the production of coagulase, and coagulase-positive strains were kept for further investigation Samples from bedding were taken by the sweep-plate technique of Blowers and Wallace (1955)

All coagulase-positive strains isolated in this way were tested for sensitivity to penicillin, streptomycin, tetracycline, chloramphenicol, erythromycin, and novobiocin by the ditch-plate method The concentrations of antibiotics used in the ditch were for penicillin 10 units per ml , streptomycin 50 or 200 µg per ml , chloramphenicol 50 µg per ml , and tetracycline, erythromycin, and novobiocin 25 µg per ml The Oxford staphylococcus was streaked across each plate as a control Strains were recorded as sensitive if they showed a degree of sensitivity similar to that of the Oxford staphylococcus, resistant if they grew up to or across the ditch, and partially resistant if there was an intermediate degree of inhibition

Representative strains were phage-typed by the method of Williams and Rippon (1952) using 21 phages

Outbreak in Medical Ward

This ward was first studied in November, 1957, as part of an investigation into the incidence of strains of *Staphylococcus pyogenes* in the hospital environment Nasal swabs were taken from all the patients and staff, and sweep-plates were made from the bottom and one top blanket of each patient and from one curtain round each bed

Antibiotic Sensitivity of Strains Isolated

The number of strains of *Staph pyogenes* isolated and their sensitivity to antibiotics are given in table I, which shows that strains resistant to penicillin, streptomycin, tetracycline, and erythromycin were isolated from eight blankets, three curtains, and the nasal swabs of 3 patients The bedding of 7 patients was involved, 4 of whom were not apparently harbouring this type of staphylococcus in their anterior nares Where strains with other patterns

TABLE I—STRAINS OF STAPH PYOGENES ISOLATED FROM MEDICAL WARD

R, resistant. S, sensitive.
* Figures in parentheses show number of specimens yielding *Staph. pyogenes*

of resistance to antibiotics were found in bedding, in most cases this was in association with nasal carriage Strains resistant to more than one antibiotic were not isolated from any of the staff

All the strains were also tested for sensitivity to chloramphenicol and novobiocin. All were sensitive to novobiocin, but 2 of the 14 erythromycin-resistant strains were also resistant to chloramphenicol, and 2 of the other erythromycin-resistant strains yielded chloramphenicol-resistant variants

Phage-typing Results

Of the 14 erythromycin-resistant strains 13 were tested for sensitivity to bacteriophages and showed an identical pattern 53/75/77

Of the strains resistant to penicillin, streptomycin, and tetracycline but sensitive to erythromycin 7 were found to be of five different types, all of group III 21 strains resistant to penicillin only were of ten different types, comprising strains of each of the three main phage-groups

Source and Spread of Epidemic Strain

It seems clear from the foregoing results that a single strain of staphylococcus resistant to penicillin, streptomycin, tetracycline, and erythromycin was spreading round the ward The 7 patients whose bedding was infected were not confined to any one area The blankets of 5 patients, including 2 of the 3 nasal carriers, yielded only a few *Staph pyogenes* The 6th patient (A) had a top blanket heavily contaminated with this organism, but no coagulase-positive staphylococci were isolated from his nose, his bottom blanket, or the curtain surrounding his bed Subsequently he was found to have a facial dermatitis infected with the epidemic strain

In the 7th patient a heavy growth of the organism was isolated from his nose, both blankets, and the curtain round his bed He had eczema of one leg with a generalised infected sensitisation dermatitis, and a heavy growth of the epidemic strain was obtained from skin swabs He had been in the ward six weeks and had been treated with prednisone and corticotrophin together with penicillin and streptomycin and later with tetracycline For the last week he had been up for part of the day and allowed to wander round the ward. It seems almost certain that he was responsible for the dissemination of the erythromycin-resistant staphylococcus There is, however, no evidence that he brought the organism into the ward with him. He had been in the hospital for two months earlier in the year and had attended as an out-patient for many months He had not been treated with erythromycin.

Control

Although no infections had resulted from the dissemination of this staphylococcus, in view of its antibiotic resistant pattern it was considered highly dangerous, and steps were taken to eradicate it. The patient who disseminated the strain was discharged, and the 2 patients carrying the epidemic strain in the nose were treated with neomycin-bacitracin cream All the bedding and curtains were changed, and the clean blankets supplied were treated with a quaternary ammonium compound ('Arquad') The floor was thoroughly washed with cresol

Five days later sweep-plates were again taken from two blankets and one curtain of each bed *Staph pyogenes* was isolated from no curtains and from the blankets of only two beds From one of these, seven colonies of a strain resistant to penicillin, streptomycin, and tetracycline but sensitive to erythromycin were isolated From the other bed the epidemic erythromycin-resistant strain was isolated This bed was that of patient A, whose top blanket had previously yielded a heavy growth of this organism, although it was not isolated from the patient's nose The patient, however, was found to have a mild dermatitis of his face, and swabs from this yielded a similar staphylococcus After his discharge and his bedding had been superseded by arquad-treated blankets the strain disappeared from the ward and in the subsequent two months was never isolated from patients or bedding

Outbreak in Surgical Ward

The staphylococcal outbreak (Oct 26 to Dec. 28, 1957) in the surgical ward was very different from the one just described A single strain of *Staph pyogenes* of phage type 80 caused infections of which many were very severe and one fatal in 11 people, including 2 nurses and 1 surgeon (table II) In all the cases the strain was resistant to penicillin and tetracycline, sensitive or partially resistant to streptomycin, and sensitive to novobiocin The sensitivity to erythromycin varied, this was almost certainly due to the fact that case 1, who initially was infected with an erythromycin-sensitive organism, yielded an erythromycin-resistant variant after treatment with this antibiotic (see below) In case 8 a chloramphenicol-resistant variant was isolated, this finding is unexplained

Fatal Case

Attention was first drawn to the ward because a patient (table II, case 2) had died of a fulminating staphylococcal pneumonia

* This patient had been transferred to another ward.

He had been admitted on Nov 21, 1957, with acute intestinal obstruction He was extremely ill from his abdominal condition and also had bronchitis He was treated by aspiration and with intravenous fluids, penicillin, and streptomycin A few days later he was considered fit for operation, volvulus of the cæcum with patchy gangrene was found but no generalised peritonitis His cæcum, his appendix, and part of his ascending colon were excised, and an end-to-end anastomosis was made A course of tetracycline was started

After operation the patient made a remarkable recovery and was up and looking well when, on the eighth postoperative day, he developed acute respiratory symptoms with thick purulent sputum which was choking him Tracheotomy gave temporary relief, but his condition rapidly deteriorated, and he died within forty-eight hours of the onset of respiratory symptoms

Necropsy revealed extensive infection of his lungs, but the condition of his abdomen was satisfactory

Source of Infection

About a month previously, on Oct 26, a patient (table II, case 1) had been admitted to the ward with multiple septic spots and boils due to a strain of *Staph pyogenes* resistant to penicillin and tetracycline, partially resistant to streptomycin, and sensitive to chloramphenicol, erythromycin, and novobiocin He was treated with erythromycin alone 250 mg six-hourly for seven days to clear up his skin sepsis On the fifth day of this treatment a recurrent pilonidal sinus in his sacral region was excised On Nov 18, ten days after operation, his wound showed signs of infection, and pus from it yielded a strain of *Staph pyogenes* resistant to erythromycin, penicillin, and tetracycline, and partially to streptomycin A fortnight later he developed an inguinal abscess from which a similar staphylococcus was isolated

Subsequent investigation showed that the erythromycin-sensitive *Staph pyogenes* isolated from him on admission and the erythromycin-resistant strains isolated from the wound and the inguinal abscess some weeks later were all of the same phage type—type 80 It is therefore clear that the strain had developed resistance as a result of the seven days' treatment with erythromycin Since the strain isolated from the fatal case of pneumonia was of the same phage type, it seemed probable that this patient (case 1) was the source of infection

Staphylococci in Environment

Bedding—Sweep-plates were taken from two blankets and one curtain of each bed on Dec 5 Table III shows that *Staph pyogenes* was isolated from the blankets of 13 patients and the curtains of 12, ten of these twenty-five strains were resistant to penicillin and tetracycline, and nine others to these two antibiotics and erythromycin All the erythromycin-resistant strains, tested by bacteriophage, were type 80, and two of eight strains resistant to penicillin and tetracycline but not to erythromycin were also type 80

Staff carriers—On Dec 11 nasal swabs were taken from 10 nurses, 6 carried *Staph pyogenes*, one of the strains was sensitive to all the antibiotics tested, four were resistant to penicillin alone, and one, from the ward sister, was resistant to penicillin, tetracycline, and erythromycin This last strain was phage type 80 *Staph pyogenes* was isolated from only two nasal swabs of 11 doctors studied, and in both instances the strain was resistant to penicillin alone

Air samples—With a slit-sampler three samples of air were taken from each of four widely separated sites in the ward into nutrient agar containing phenolphthalein phosphate and tetracycline 10 µg per ml The 100 c ft of air thus sampled yielded eleven colonies of *Staph pyogenes* resistant to penicillin and tetracycline Nine of these colonies were resistant to erythromycin, and those tested were all phage type 80

Attempts to Control Infection

Case 1 was transferred to a side-ward, and the ward sister who carried the epidemic strain in her nose was treated with neomycin-bacitracin cream and permitted in the ward only when adequately masked The blankets, counterpanes, and curtains from all the beds were changed on Dec 6 For the blankets were substituted immediately blankets treated with a quaternary ammonium compound (arquad), and the curtains which had been removed were similarly treated and then returned to the ward Ten days later, sweep-plates taken from the blankets and curtains of all the beds gave the results shown in table III, which shows that, although the number yielding *Staph pyogenes* was very much smaller, one blanket and one curtain carried the strain resistant to penicillin, tetracycline, and erythromycin

Table II shows that, during this ten-day period, 2 more patients and 1 nurse developed infections due to strains of the same phage type Case 3, with a boil, had recovered from his operation and was discharged, and the nurse was sent off duty Case 5 had a very severe staphylococcal pneumonia as well as infection of an amputation stump and a transfusion wound He was transferred to a side-ward and treated with vancomycin, to which he made a dramatic response

At this stage attempts were made to spray the floor and the lower part of the walls of the ward with a quaternary ammonium compound, but, when the same strain of staphylococcus had infected the wounds of 2 more patients and the finger of 1 other nurse, it was decided on Dec 28 to close the ward Before the ward was empty, 1 further patient developed a chest infection and 1 surgeon developed an axillary abscess Finally 1 patient who had been transferred to a medical ward with pulmonary tuberculosis was found to be superinfected with the epidemic strain of staphylococcus

Nasal Carrier State of Patients and Staff at Time of Ward Closure

The nasal carrier state of patients and staff at this stage is analysed in table IV, which shows that only 6 of 20 patients carried *Staph pyogenes*, but in 2 the strains were resistant to penicillin, tetracycline, and erythromycin Of 15 nurses studied 12 carried *Staph pyogenes* 10 a strain

TABLE IV—CARRIER STATE OF PATIENTS AND STAFF ON DEC 30, 1957, IN OUTBREAK IN SURGICAL WARD

—	No examined	No carrying *Staph pyogenes*				
		Total	Antibiotic sensitivity of strains isolated			
			S to all tested	R to penicillin only	R to penicillin and tetracycline	R to penicillin, tetracycline, and erythromycin
Patients	20	6	1	3	-	2
Nurses	15	12		10	1	1
Doctors	11	4		2	2	
Domestics, porters, physiotherapy, and X-ray staff	26	9	6	3		

resistant to penicillin alone, 1 to penicillin and tetracycline, and 1 to these two antibiotics and erythromycin This last was not the ward sister but a nurse who, when tested on Dec 11, was carrying a strain sensitive to all the antibiotics tested Of 11 doctors tested 4 carried *Staph pyogenes* 2 of the strains were resistant to penicillin only, and 2 to penicillin and tetracycline The group consisting of domestics, porters, and the staff of special departments, whose contact with patients was slight, is of interest in that most of the strains isolated were sensitive to all the antibiotics tested

Effect of Closure of Ward and Spraying with Cetrimide

Those patients well enough to go home were discharged, 2 patients still infected with the epidemic strain were transferred to a fever hospital, and the 9 remaining patients, after their nose, skin, and bedding had been shown to be free from the infecting staphylococcus, were sent to other wards of the hospital The whole ward, including side-rooms and corridor, was then thoroughly sprayed with cetrimide

Air-dust samples—In the next four days the air of the ward was sampled by exposing petri dishes containing nutrient agar plus phenolphthalein phosphate for two and a half hours Swabs were also taken from the dust on the floor and plated out on a similar medium In the main ward 49 plates were exposed and 24 dust swabs examined Of the 73 plates thus used penicillin 10 units per ml was added to the medium in 23, erythromycin in 26, and no antibiotic in 24 No colonies of *Staph pyogenes* were isolated from any of these plates

Similar tests were made in the side-rooms and the adjoining corridor, these consisted of three side-wards, kitchen, bathroom, sluice, linen-room, office, and laboratory In each room 2–4 plates were exposed and 2 dust swabs were taken, in the corridor 5 plates were exposed and 3 dust swabs taken. In all, 49 plates were used 18 contained penicillin, 19 erythromycin, and 12 no antibiotic No *Staph pyogenes* was isolated from the dust swabs, but 2 of the exposed plates yielded coagulase-positive staphylococci One of these, containing penicillin, had been exposed in the linen-room and yielded two colonies, the other, containing erythromycin, had been exposed in the corridor just outside the linen-room and yielded one colony All three colonies were of the epidemic type

In view of the negative results obtained everywhere except in the linen-room, in spite of the rather searching tests in which large numbers of plates had been exposed for two and a half hours, it was decided to fumigate the linen-room without retreatment of the rest of the ward Twenty-four hours after this had been done, 9 plates without antibiotic were exposed for two and a half hours in the linen-room and the adjoining corridor Four colonies of *Staph pyogenes* were isolated from 1 plate exposed in the corridor Since none of these was resistant to any other antibiotic than penicillin, it was decided to reopen the ward

Bedding—The beds were all made up with linen and blankets treated with arquad, and similarly treated curtains were supplied Sweep-plates were taken from two blankets and one curtain of each bed before the admission of patients *Staph pyogenes* was isolated from one blanket and one curtain In each case only a single colony was found, that from the blanket was sensitive to all the antibiotics tested, and that from the curtain was resistant to penicillin only

Discussion

In each of these outbreaks a single strain of *Staph pyogenes* resistant to penicillin, tetracycline, and erythromycin was widespread in the ward environment, and in each case there is evidence that the strain was introduced into the ward by a patient with superficial skin sepsis Although the epidemic strain was isolated from the sister in the surgical ward, more probably she was a reflection of the epidemic than its cause, since strains of *Staph pyogenes* resistant to erythromycin had not been found in this ward before the admission of case 1 and were very uncommon elsewhere in the hospital None such had been found when nasal swabs from 540 nurses were examined ten weeks previously

The outbreak in the medical ward was associated with no severe sepsis, and the strain was apparently eradicated by removing the infected patient, treating the nasal carriers, and changing all the blankets for those treated with a quaternary ammonium compound In the surgical ward, however, there were 11 cases of infection, many of them severe, and the strain was eliminated only after closure of the ward and spraying with cetrimide

Probably both the host and the parasite played a part in this difference As regards the host, patients after operations are highly susceptible to infection McDermott (1956) has suggested that an " increased congregation of more susceptible hosts " is one of the main reasons for the apparent increase in staphylococcal infections in hospitals today

The virulence of the invading staphylococcus must not, however, be overlooked *Staph pyogenes* of phage type 80, the type responsible for the outbreak in the surgical ward, was first isolated in 1953 by Rountree and Freeman (1955) in Australia They regarded the strain as a new phage type of *Staph pyogenes* of " enhanced virulence ", because of the severity of the lesions and the predominance of this strain in outbreaks of neonatal infection in 1954 throughout Australia Since then other workers have reported outbreaks of unusually severe staphylococcal infection due to strains of this type in Great Britain (Anderson and Williams 1956, Gillespie and Alder 1957, Duthie 1957)

It cannot be assumed from this that strains of certain phage types are necessarily more virulent than those of other types Probably the virulence of most strains of *Staph pyogenes* may become enhanced in infections (Barber and Burston 1955) and by passage through patients (Rountree and Freeman 1955, Beaven and Burry 1956)

Antibiotic Sensitivity of Infecting Strains

In the surgical ward the infecting strain was initially erythromycin-sensitive but yielded an erythromycin-resistant variant during the treatment of 1 patient with this antibiotic for seven days Such occurrences are well known with erythromycin (Wise et al 1955, Thomson et al 1956), and Hobson (1954) and Garrod and Waterworth (1956) have shown that staphylococci produce strains resistant to erythromycin more readily than they produce strains resistant to any other antibiotic except streptomycin

In both wards an occasional variant resistant to chloramphenicol was found This finding is unexplained, and there is no known correlation between resistance to erythromycin and resistance to chloramphenicol Since both the infecting strains were resistant to several antibiotics, it is possible that they were highly mutagenic Chadduck et al (1954), working with *Escherichia coli* K 12, have shown that certain strains of this species have mutator genes, which give them an increased rate of mutation to drug resistance and other characteristics The same may be true of staphylococci

Preventive Measures

As long as septic cases are admitted to general wards, hospital cross-infection will continue The present study shows the importance of superficial skin infections in this respect and confirms the observation of Barber and Bursten (1955) that nasal carriers may be relatively unimportant In both wards numerous strains of *Staph pyogenes* were present in the environment, but a newly introduced strain spread round the ward to a much greater degree than any of the strains previously present It is improbable that all strains of *Staph pyogenes* could be excluded from a ward, but, if we really face the fact that staphylococcal sepsis is a communicable disease, there is nothing to prevent hospitals from having isolation blocks to deal with this problem

Meanwhile something, no doubt, can be done by barrier nursing and by treating the bedding The difficulty of applying the former adequately in a busy general ward is, however, extreme The danger of blankets as a source of infection can be reduced Barnard (1952) showed that they were not only sterilised by impregnation with estyl pyridinium bromide ('Fixanol C') but also remained, to some extent, self-disinfecting Blowers and Wallace (1955) and Frisby (1957) recommended washing the blankets in a non-ionic detergent ('Lissapol') and then soaking with a cationic detergent ('Currasol') In the present study arquad was the quaternary ammonium compound used

Finally the whole hospital policy in relation to staphylococci needs reviewing It would almost certainly be impossible and not necessarily desirable to eliminate the whole genus from the hospital environment It might be more sensible and would certainly be more practicable to select relatively harmless strains There is much evidence that pathogenic and non-pathogenic staphylococci are variants of a single species, and that white, golden, or even lemon-yellow strains may, under certain rare conditions, arise one from another (Hoffstadt and Youmans 1932, Pinner and Voldrich 1932, Barber 1955) Certainly strains of staphylococci may show all permutations or combinations in relation to the production of pigment and of alpha-lysin, coagulase, and other toxic substances (Barber et al 1953)

The haphazard and wholesale use of antibiotics in hospitals in the last fifteen years has selected strains of staphylococci which are not only resistant to many of these powerful weapons but also, possibly because they have been freed from competition with lesser breeds, liable to give rise to strains of enhanced virulence (Howe 1954, Beaven and Burry 1956, Barber 1958) A hospital antibiotic policy designed to reverse this process, in association with the exclusion of multiple-resistant strains from the general wards, might have far-reaching results It may well be that the best approach to the problem of staphylococcal cross-infection is to learn how to select staphylococci of lower infectivity and virulence and to render human beings more resistant to their toxic products In the New Jerusalem, when the lion lies down with the lamb, is it too much to hope that man will have learnt to live at peace with the staphylococcus?

Summary

Staphylococcal outbreaks in a medical ward and a surgical ward are described Each was due to the admission of a patient with superficial staphylococcal infection

In both outbreaks the offending staphylococcus was resistant to erythromycin as well as to penicillin, streptomycin, and tetracycline, and in one outbreak the erythromycin resistance followed treatment of the initial patient with this antibiotic

In the medical ward, although the bedding of 7 patients, in widely scattered areas of the ward, was infected, there were no cases of severe sepsis After the infected patients had been discharged and all the blankets and ward curtains had been superseded by fabrics treated with a quaternary ammonium compound, the epidemic strain was no longer found

In the surgical ward a single strain of *Staph pyogenes* of phage type 80 caused severe infections (of which one was fatal) in 8 patients, 2 nurses, and 1 surgeon The offending strain was only eliminated by closing the ward and by spraying with cetrimide

It is a pleasure to thank the many colleagues, especially Nurse H M Higham, who not only made this investigation possible but also assisted us in every way, and Dr R E O Williams and Dr Patricia Jevens, of the Central Public Health Laboratory, Colindale, for phage typing many of the strains and supplying us with bacteriophages so that we could continue for ourselves

HEAD OF THE CLINICAL RESEARCH UNIT

From the Clinical Research Unit of the Walter and Eliza Hall Institute of Medical Research and the Royal Melbourne Hospital, Victoria, Australia

There have been many excellent reports of the macroscopic appearance of the tongue in disease (Sircus et al 1957), particularly of its value as an indication of deficiency of riboflavine, nicotinic acid, and protein (Spies et al 1938). In pernicious anæmia, the appearance of the tongue improves after the administration of cyanocobalamin vitamin B^{12} (Brown 1949)

In Australia Bolton and his colleagues have made valuable studies of the appearance of the tongue in malnutrition and pregnancy (Bolton 1958, Bolton and Forster 1958) and have correlated the changes with the neurological findings (Bolton 1955) and the level of serum-albumin (Gandevia and Hossack 1955)

A survey of the recent literature available to us has revealed no such studies based on biopsies of the epithelium of the tongue, though tongue biopsy has been used to investigate local lesions such as cancer

Our purpose here is to describe our experience with tongue biopsy, with special reference to a new biopsy tube designed in our unit It is a modification of the flexible suction gastric biopsy tube first described by two of us (Wood et al 1949)

Only a limited report can be given of the histological findings a full discussion will be published when further data become available, especially concerning serial biopsies in 1 patient

The study was begun by using fine scissors to cut small fragments of epithelium, but this proved unsatisfactory, especially when the central zone was being examined It was difficult to obtain sufficient depth without causing the patient subsequent discomfort by exposing too great an area After 17 biopsies had been cut with fine scissors with only moderate success it became apparent that a suction biopsy tube would be preferable, because it would remove a full depth of epithelium and some underlying substantia propria from a limited area Following a number of trials a rigid suction tube was designed which produced suitable fragments

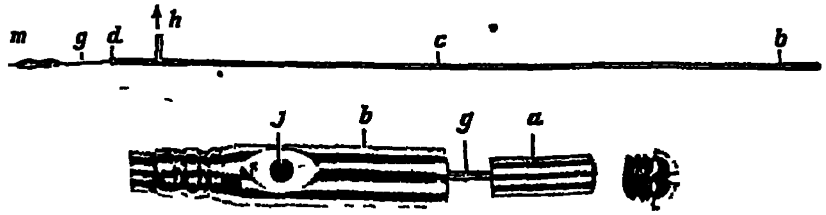

Fig 1—Rigid suction-tube for tongue biopsy, with details of operating head

The Tube

The tube† (fig 1) consists of a cylindrical knife (a) and head (b) about 3 cm long and 6 mm outside diameter rigidly mounted on one end of a stainless-steel tube (c) 41 cm long and 4 mm in diameter The proximal end is fitted with a suction-tight gland (d) and a lateral tube (h) through which suction is applied The knife (a) 11 mm long and 4 mm diameter has a proximal cutting edge and is screwed on to the end of a 19-gauge spring steel wire (g), which traverses the length of the tube and emerges through the gland at the proximal end where it is fitted with a detachable handle (m) A hole (j), 2 mm in diameter, countersunk to a maximum diameter of 7 mm , is drilled laterally in the wall of the head (b) A terminal screw seals the end of the head, and when unscrewed allows the knife to be detached The outside wall of the head, diametrically opposite the hole, is marked to permit accurate location of the hole on the tongue On operation a suction of 40 cm Hg is applied, a small fragment of tongue is sucked into the hole (j) and is cut off when the knife is operated

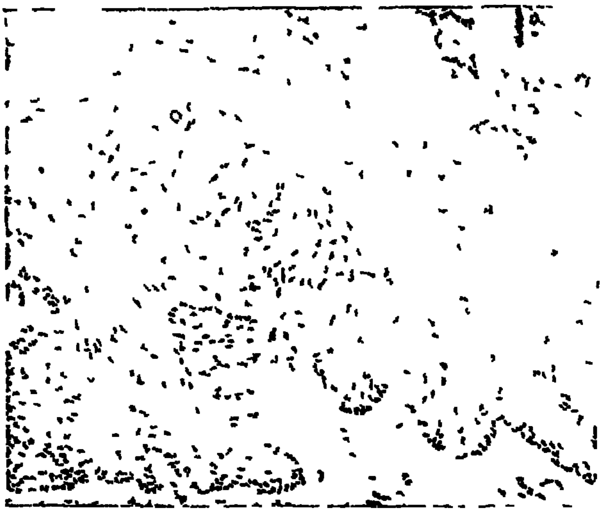

Fig 2—Biopsy of normal tongue Actively proliferating basal cells lie between primary and secondary papillæ in substantia propria , prickle cells are numerous , superficial squamous cells have formed filiform papillæ, and groups of cocci are visible on desquamating cells in upper right-hand corner (Hæmatoxylin and eosin × 150)

Technique

The patient lies with his head supported by a pillow The operator sits on his left and grasps the tip of the protruded tongue after wrapping it in gauze The area selected is swabbed with benzalkonium chloride and alcohol, and then 3% cocaine in 1 10,000 adrenaline A fine needle (26 gauge) is inserted at an angle of about 30° and 0 3 ml of procaine 2% solution is slowly injected below the epithelium

The biopsy tube is applied lightly and accurately over the area of anæsthesia, the position of the lateral hole being indicated by the location mark on the instrument The proximal end of the tube is held by an assistant, who depresses the operating handle to open the lateral hole, applies negative pressure to suck in the fragment, and immediately pulls up the knife blade This operation may be repeated over a neighbouring site to obtain a second fragment The fragment is retrieved by removing the terminal screw and unscrewing the cylindrical blade A fragment remaining in the cylinder may be blown out by a stream of air

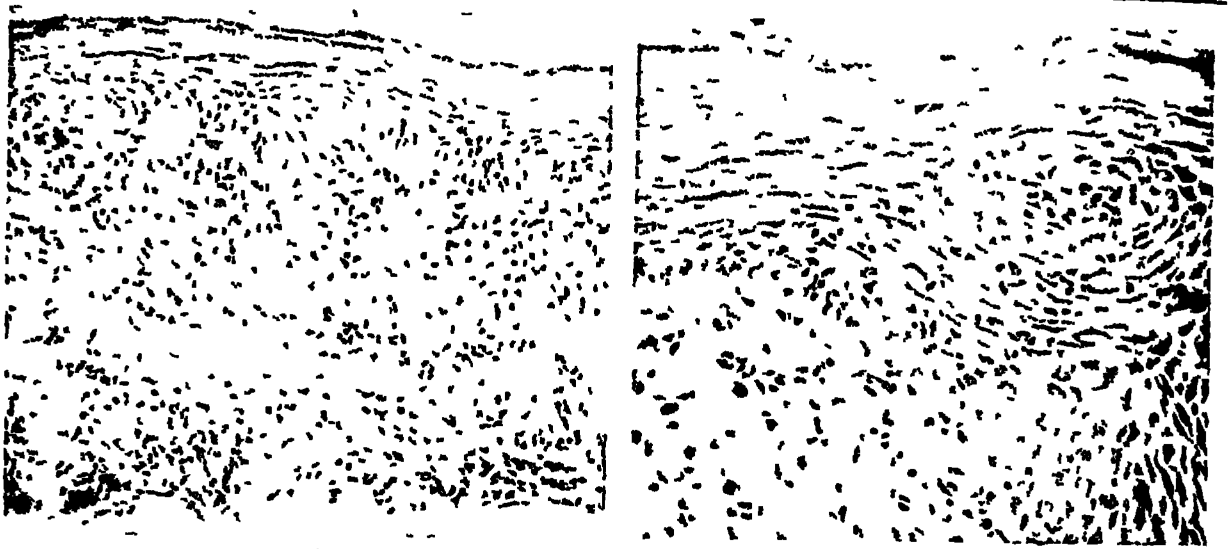
* Working with the aid of a grant from the National Health and Medical Research Council of Australia

† This biopsy tube is made by H A Taylor and Son (Surgical) Pty Ltd, 44, Macfarlan Street, South Yarra, Melbourne, Victoria, Australia



(A) (B)

Fig 3—Tongue biopsy in atrophic glossitis Woman, aged 45, with chronic hepatitis, malnutrition and recurrent glossitis Tongue was painful, ulcerated, red, and smooth A, gross thinning of epithelium and loss of filiform papillæ, while primary and secondary papillæ have disappeared, heavy inflammatory infiltration of substantia propria and epithelium (Hæmatoxylin and eosin × 300) B, thin basal and prickle-cell layers of epithelium and infiltration of substantia propria and penetration of epithelium by lymphocytes (Hæmatoxylin and eosin × 600)

The fragment is immediately fixed in 10% formol saline and when embedded in paraffin, oriented to obtain a vertical section of the mucosa

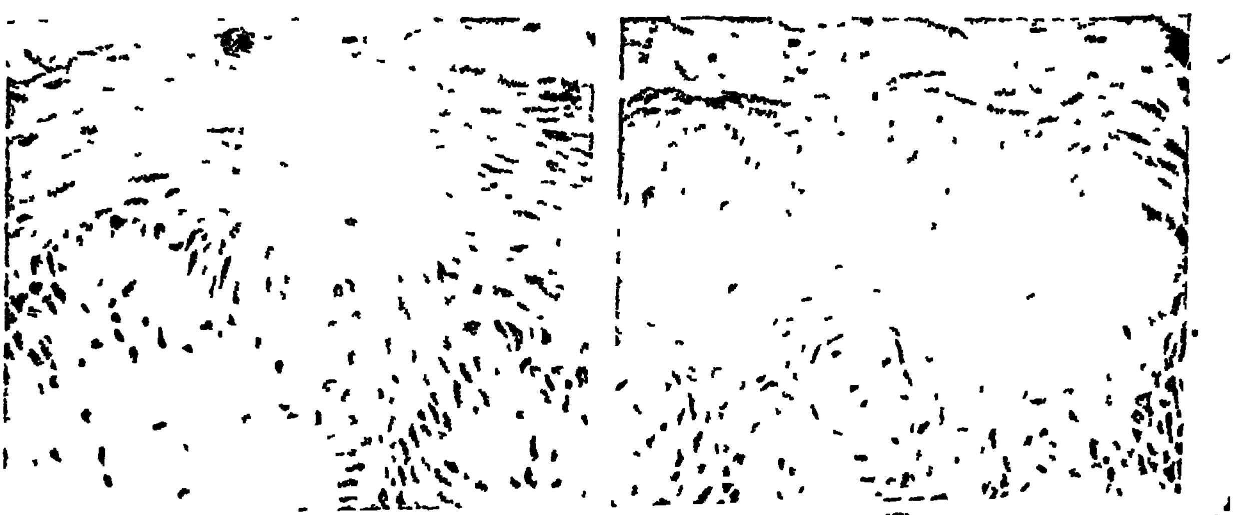
Results

With this model 50 successful biopsies have now been made at 53 attempts on 40 people whose tongues either appeared normal (17) or showed atrophy or inflammation (33) The specimen was usually taken from an area about 2 cm from the tip and mid-way between the median groove and the lateral edge On 18 occasions two fragments were obtained from neighbouring sites 6 people had further biopsies a week or more later, 1 having 4 biopsies, 2 having 3, and 3 having 2 The 3 failures were all in people with considerable atrophy of the epithelium—1 with pernicious anæmia, 1 with recurrent glossitis, and 1 with malnutrition and atrophic glossitis In 2 of these, small fragments were subsequently obtained by fine scissors, but this was difficult and caused relapse in the case of ulcerative glossitis

In the 50 successful biopsies when the suction tube was used, no major discomfort was felt either during or after the operation Most subjects reported no discomfort, a few had slight soreness of the tongue for twenty-four hours

Pathology of Biopsy Fragments

Biopsies of the anterior upper surface of the normal tongue presented an appearance in keeping with standard descriptions (Maximow and Bloom 1948), the three layers (superficial squamous, prickle, and basal) being clearly identified Certain regions showed evidence of more rapid proliferation of the basal cells, these cells forming a layer three to six cells thick and being cuboidal



(A) (B)

Fig 4—Tongue biopsy, showing glossal atrophy Woman aged 51, with untreated pernicious anæmia Tongue was red, smooth and atrophic A, considerable thinning of epithelium Basal layer is only one or two cells in depth and few prickle cells remain There is thin smooth superficial squamous-cell layer (Hæmatoxylin and eosin × 600) B, after treatment with vitamin B_{12} for six weeks Basal-cell proliferation is more pronounced, numerous prickle cells are present Keratohyaline granules are visible in superficial squamous-cell layer (Hæmatoxylin and eosin × 600)

or low columnar in shape, with darkly staining oval nuclei and scanty cytoplasm (fig 2) More superficially the cells were prickle-cell in type, forming a layer about six cells thick Here the cells were oval or spindle-shaped, with paler staining and irregularly shaped nuclei, and peripheral intercellular bridges visible under higher magnification More superficially again there was a squamous-cell layer, often containing keratohyaline granules At the surface these cells formed filiform papillæ, whose surface was roughened by desquamating cells which often contained groups of cocci (fig 2) Biopsy on "furred" tongues showed excess amounts of this superficial cellular material and cocci Over fungiform papillæ the surface was smooth

In regions where basal-cell proliferation appeared less active, the basal-cell and prickle-cell layers were only one or two cells in depth, while the squamous layer was thin and smooth Under these areas the substantia propria projected up to form primary and secondary connective tissue papillæ These normally contained some thin-walled capillaries and an occasional fibroblast and mononuclear cell (fig 2)

When there was macroscopic glossal atrophy good general correlation was found with the histological appearances Here the areas of slower basal-cell proliferation were increased and tended to coalesce, with a corresponding reduction or disappearance of the regions of rapidly multiplying basal cells (fig 3) This produced a thin smooth mucosa in which filiform papillæ had disappeared all three layers of the stratified squamous epithelium were reduced in width and the primary and secondary connective-tissue papillæ were absent

Biopsy of a tongue showing moderate macroscopic atrophy revealed loss of the filiform papillæ and decrease in prickle cells, with gross macroscopic atrophy there was thinning of all epithelial layers and absence of the papillæ of the substantia propria

With atrophy of the epithelium the coccal colonies disappeared, possibly because of a decrease in the supply of nutritional factors afforded by the normally desquamating cells Such a decrease in the normal bacterial flora and a reduction of the mechanical barrier may predispose the tongue to bacterial infection and inflammation

In a case of pernicious anæmia with considerable atrophy of the epithelium, the biopsy was repeated after six weeks of treatment with vitamin B_{12} (fig 4) Even allowing for slight variation in the cutting angle of the sections, there was an increase in the thickness of the basal and prickle-cell layers, and keratohyaline granules had formed in the squamous layer The connective-tissue papillæ were also increased in depth

The only inflammatory changes observed in this series were an increase in the lymphocytes, plasma cells, and mononuclear cells in the substantia propria Lymphocytes were frequently seen penetrating the epithelium, lying in small vacuoles between the cells (fig 3)

Discussion

In this limited experience there was good correlation between the appearance of atrophy of the tongue and the biopsy findings When the tongue appeared normal, the biopsy revealed stratified squamous epithelium which could be seen as a plate of proliferating basal cells' In some areas proliferation appeared to be more rapid than in others, producing an uneven epithelial layer With the development of atrophy the basal-cell proliferation became slower and more even, thus producing a thin smooth epithelium

In 1 case of pernicious anæmia the administration of vitamin B_{12} was followed by a cellular response towards a more normal epithelium—a change parallel to that seen in other proliferating cells such as the hæmopoietic bone marrow, but absent in the gastric mucosa (Doig and Wood 1950, Finckh and Wood 1953)

It may well be that studies based on biopsy of the tongue will throw further light on the degenerative processes in various diseases, especially with regard to the cellular changes Serial biopsies on a single patient may also produce critical evidence of the value of various therapeutic measures

Summary

A rigid suction tongue-biopsy tube is described

50 successful biopsies were made in 40 people whose tongues either appeared normal or showed atrophy or inflammation There was no major discomfort either at operation or later

The fragments obtained were suitable for histological examination There was a full depth of epithelium with some underlying substantia propria When the tongue appeared atrophic there was good correlation between macroscopic and histological appearances

Studies based on biopsy of the tongue may throw further light on the degenerative processes in various diseases, especially with regard to the cellular and tissue changes Serial biopsies may aid in assessing the value of treatment

Our thanks are due to the members of the honorary medical staff of the Royal Melbourne Hospital for sending patients for examination, to Miss E Earle for skilfully preparing the histological specimens, and to Mr R Inglis, photographer to the Royal Melbourne Hospital, for providing fig 1

COMPOSITION OF PLASMA CHOLESTEROL ESTER

IN RELATION TO CORONARY-ARTERY DISEASE AND DIETARY FAT

BARRY LEWIS
M.D, Ph.D Cape Town, A.R.I.C

From the Department of Medicine and the Clinical Nutrition Research Unit, University of Cape Town

THE fatty acids of cholesterol esters (C.E.F.A.) in plasma are highly unsaturated (Bloor et al 1938, Kelsey and Longenecker 1941, Michalec 1956), the mean iodine value (I.V.) in man being 157 8 in Bloor's series Prominent among the unsaturated C.E.F.A. are linoleic and (to a lesser extent) arachidonic and linolenic acids, which are essential in that they cannot be synthesised in the mammalian body from saturated fats or acetate and that pathological changes take place in some animals fed on diets deficient in them Many vegetable oils containing a preponderance of these fatty acids have the property of lowering the serum-cholesterol (Ahrens et al 1955), Frishley et al 1955, Bronte-Stewart et al (1956), appar-

FATTY ACIDS OF CHOLESTEROL ESTER OF PLASMA IN NORMAL BANTU AND WHITE SUBJECTS, AND IN PATIENTS WITH CORONARY-ARTERY DISEASE (EXPRESSED AS MEAN AND STANDARD DEVIATION)

—	Bantu	White	Coronary-artery disease
Ester cholesterol (mg per 100 ml)	91 (32)	141 (12)	151 (31 5)
Iodine value	179 (26 5)	160 (34 5)	136 (35 6)
% Linoleic	55 4 (10 8)	53 2 (10 7)	40 6 (15 5)
% Linolenic	8 6 (4 3)	5 1 (2 5)	5 4 (2 8)
% Arachidonic	13 6 (4 9)	9 5 (2 3)	7 6 (3 0)

% Hexaenoic	3 2 (2 0)	2 5 (2 7)	2 8 (2 7)
% Saturated + oleic	18 0	28 3	41 5

ently by accelerating the catabolism of this sterol to bile acid (Lewis 1957, 1958)

Studies on *total* serum fatty acids have been reported from several centres Wiese et al (1956) have found that trilinolein feeding increases the percentage of linoleic and arachidonic acids Hammond and Lundberg (1955), comparing Guatemalans on low fat intakes, atherosclerotic subjects, and blood-bank donors, demonstrated lower percentages of linoleic and arachidonic acids, but a probable higher percentage of linolenic acid, in the atherosclerotic group Also employing the technique of alkali isomerisation for the analysis of polyunsaturated fatty acids, Antonis (1957) reported a lower percentage of linoleic acid in atherosclerotic patients than in normal white subjects, while Bantu mine labourers had far higher percentages of linoleic and arachidonic acids On the other hand, James et al (1957) were unable to demonstrate an abnormality of serum fatty acids in patients with coronary-artery disease, using vapous phase chromatography as the analytical procedure In interpreting these studies it should be noted that total serum fatty acids may not represent a homogeneous physiological entity

These interrelationships suggested an investigation into plasma C E F A composition in coronary-artery disease, and as a corollary, in Bantu subjects, whose susceptibility to this condition is exceedingly low * Feeding experiments have been carried out to ascertain whether plasma C E F A were affected by the nature of the dietary fat C E F A from atheromatous coronary arteries have also been analysed

Twelve white patients who had had one or more cardiac infarctions were studied They were ambulant, and were selected in that their dietary habits (so far as could be ascertained) had not been changed after their illness, at the time of the survey none was receiving anticoagulant therapy Twelve Bantu subjects were investigated they were clinically normal, and care was taken to exclude any whose dietary and other customs might have been modified by urbanisation Eight white subjects, clinically and electrocardiographically normal, served as controls The samples were analysed without prior knowledge of the group to which they belonged The mean ages of the three groups were 40, 35 5, and 48 years respectively

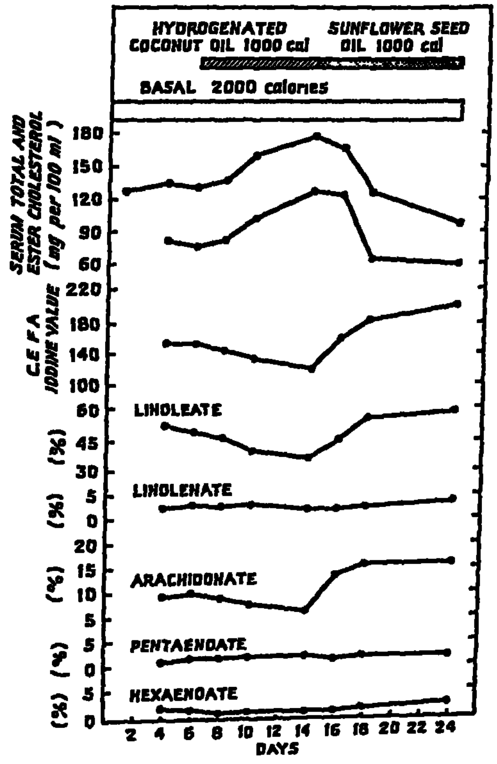
Plasma was extracted within one hour of venesection, using ten volumes of methylal-methanol 4 1 (Delsal 1944) The total lipid was fractionated according to the procedure of Fillerup and Mead (1953) by chromatography on silica gel, previously deactivated and washed with methanol and ether containing 0 1% hydroquinone to remove adsorbed oxygen, and finally washed with petroleum ether Saponification of cholesterol esters was carried out at 35°C using potassium *tert*-butoxide, cholesterol was removed, the soaps were hydrolysed, and the fatty acids extracted conventionally Fatty acids were determined by electrometric titration to pH 9 0 with 0 01N ethanolic potassium hydroxide, assuming a mean molecular weight of 286 A micro-bromine addition procedure (Trappe 1938) provided a measure of overall unsaturation, and poly-unsaturated fatty acids were characterised and determined by the alkali isomerisation technique of Herb and Riemenschneider (1953), saturated plus oleic acids were computed by difference All operations were performed in a nitrogen atmosphere

As the table shows, C E F A iodine values were highest in the Bantu group and lowest in the patients with coronary-artery disease This was due mainly to differences in linoleic and in arachidonic acid percentages, and reciprocally in saturated (mainly palmitic by paper chromatography) plus oleic acids The coronary group had the highest and the Bantu the lowest total lipid levels

Application of the t test showed that the differences between the C E F A iodine values of the three groups were *significant at the 5% level*, that between the Bantu and coronary groups being almost significant at the 1% level The differences between the percentages of arachidonic acid were also significant at the 5% level, but linoleic acid differed significantly only between white and coronary and between Bantu and coronary groups

Feeding experiments were carried out on two normal Bantu subjects in the metabolic ward The basal diet contained 5 g of fat Dietary oils were substituted isocalorically for carbohydrate Administration of hydrogenated coconut oil (I V 6) and sunflower-seed oil (I V 135) was shown to produce wide variations in C E F A unsaturation In the experiment shown in the chart, the C E F A iodine value fell to 122 during coconut-oil feeding and rose to 199 when this was replaced by sunflower-seed oil Linoleic and arachidonic acids were the most labile Administration of the latter oil elevated the percentage of these acids in C E F A before the serum-cholesterol fell significantly

Atheromatous coronary arteries were found to contain relatively saturated C E F A Using similar analytical techniques, a mean I V of 64 was obtained in material



---

* Several other biochemical, hæmatological and clinical modalities were investigated by Dr C Merksey, Dr H Gordon, Dr R Lackner, and Dr H Nossel These will be published separately

from four autopsies, 81% of the C.E.F.A. comprised saturated and oleic acids, the percentages of acids with two, three, four, five, and six double bonds being 11, 3.3, 3.6, 0.31, and 0.43 respectively This finding agrees with the observations of Schönheimer (1926) and Keegan and Gould (1953), who found the predominant fatty acids in human aortic plaques to be stearic, palmitic, and oleic. There is a possible parallel to this example of a higher degree of saturation of tissue-C.E.F.A in comparison to circulating esters Alfin-Slater et al (1954), working on rats, have found that deficiency of essential fatty acids leads to deposition of cholesterol and fat in the liver Achaya et al, cited by Deuel (1955), have shown further that under these conditions liver-cholesterol, normally esterified to a large extent with oleic acid, becomes bound to saturated acids

Using the data obtained in the survey, regression equations were calculated for plasma ester-cholesterol against C.E.F.A. iodine value, and against the percentages of linoleic, arachidonic, and palmitic plus oleic acids in plasma C.E.F.A. The correlation coefficients for the same data were all significant at the 5% level by Fisher's z test. This corresponds to the observation, in the feeding experiments, of a reciprocal relation between plasma ester cholesterol and the content of certain unsaturated fatty acids in plasma cholesterol esters

The regression lines for these sets of variables were somewhat dissimilar in the three groups studied, but the differences in slope were not statistically significant

Thus the proportion of saturated and oleic acids in the C.E.F.A. was far higher in atheromatous plaques than in plasma, while in plasma itself it was highest in subjects with established coronary-artery disease and lowest in the Bantu In the light of these studies it seems possible that a primary effect of dietary unsaturated fats is to increase the unsaturation of circulating cholesterol esters, perhaps rendering their solution in plasma more stable or making the cholesterol more susceptible to catabolism to bile acid However, the high concentration and probable functional importance of poly-unsaturated fatty acids in intracellular organelles (Kretchmer and Barnum 1951) have also to be considered Feeding a diet rich in such acids may conceivably facilitate certain metabolic activities, including cholesterol catabolism

This study was carried out as part of the programme of the Clinical Nutrition Research Unit supported in the University of Cape Town by the South African Council for Scientific and Industrial Research It is a pleasure to acknowledge my indebtedness to Dr H Gordon for his invaluable assistance in selecting the clinical material for the survey, to Prof J F Brock and Dr C Merskey for their encouragement, and to Mrs L Rose-Innes for technical assistance

CHRONIC DISSECTING ANEURYSM OF THE AORTA DIAGNOSED BY AORTOGRAPHY

H H G Eastcott
M S Lond, F.R.C.S
SURGEON

David Sutton
M.D Manc., M.R C.P, F.F.R.
RADIOLOGIST

ST MARY'S HOSPITAL, LONDON, W.2

Dissecting aneurysms of the aorta usually run a rapid clinical course and are often fatal within twenty-four hours Shennan (1934) examined 143 recent dissecting aneurysms and found that 84% of the patients died within the first week. However, it is now well recognised that patients occasionally recover from the initial episode and may live for many years with the condition unrecognised According to Drury (1955), who reported 2 such cases, most of the healed aneurysms described fell into a surprisingly uniform pattern. Most are " double-barrelled aortas " extending from the distal part of the arch of the aorta to the bifurcation They show clear evidence of patency, and their sacs become lined with endothelium and may contain varying degrees of atheromatous change

It is difficult to assess the real frequency of healed aneurysms of the aorta Weiss et al (1940) estimate that one dissecting aneurysm in ten is apt to heal

It is clear from the literature that a correct diagnosis of chronic dissecting aneurysm is rarely made during life Even less commonly is positive proof of the diagnosis obtained before necropsy For these reasons the following case is considered worthy of recording

Case-report

On Oct. 8, 1952, a painter, aged 43, was seized with a severe pain in the chest and back while drinking a cup of tea. The pain was continuous but was worse with breathing He remembered having a similar pain twenty years before, after an accident. On admission to University College Hospital, he was pale, and in obvious pain, but was not shocked. The blood-pressure was 130/80 mm. Hg, but rose within a few hours to 210/130 and thereafter remained at about this level The pain gradually lessened, and after a week, with a morning pyrexia, the patient seemed fairly well again. An electrocardiogram on admission and another next day proved normal.

Blood-culture during the first twenty-four hours grew a non-hæmolytic streptococcus A leucocyte-count of 14,000, with 82% polymorphs, was found on admission. The diagnoses considered were small dissecting aneurysm, spontaneous perforation of the œsophagus, and Bornholm disease. Several radiographs of the chest, taken after admission, showed a slight increase in the breadth of the mediastinum, which was thought to be significant. A clinical diagnosis of dissecting aneurysm was made His recovery was uneventful, and he was discharged perfectly fit four weeks after admission, but without a firm diagnosis

He returned home and to his work, and remained well until the following year when he collapsed and was admitted to Hillingdon Hospital Shortly afterwards he had a large hæmatemesis He was treated medically and recovered well Duodenal ulceration was diagnosed after a barium-meal examination. He remained well on an ulcer regime until 1956

During 1956 he developed a bloated feeling in the abdomen, and was found to have a pulsatile abdominal swelling which was thought by Mr J R. Elder to be an aortic aneurysm.

On admission to St. Mary's Hospital on June 26, 1956, he appeared to be in fairly good health The pulsatile abdominal swelling could easily be felt below and to the left of the umbilicus The blood-pressure was 220/120, and the apex beat was displaced to the left. No hypertensive changes were noted in the fundi, and the urine contained no albumin The blood-urea was 36 mg per 100 ml On June 29, lumbar aortography was performed by Dr D F Reynolds of the radiological department, to define the exact site and size of the suspected aneurysm, and showed the rather unusual appearances illustrated in fig 1 These gave rise to some controversy but were finally attributed to a dissecting aneurysm It was thought that the needle point had entered the sac of the aneurysm which was clearly visualised, and that the contrast medium was then entering the true lumen of the aorta, which was also shown, though less clearly, on the serial films It was suggested that the diagnosis could be confirmed and the true lumen of the aorta adequately shown by retrograde catheterisation from the femoral artery, and this was done by one of us (D S) on July 25 The aorta was readily catheterised, and contrast injections showed the appearances illustrated in fig 2 These confirm that the true lumen of the aorta was separate from the lumen of the dissecting aneurysm demonstrated by lumbar aortography and was somewhat compressed by it They suggested that the dissecting aneurysm began somewhere in the region of the aortic arch and finished in the region of the common iliac arteries They also suggested that the dissecting aneurysm was interfering with the blood-flow to the kidneys

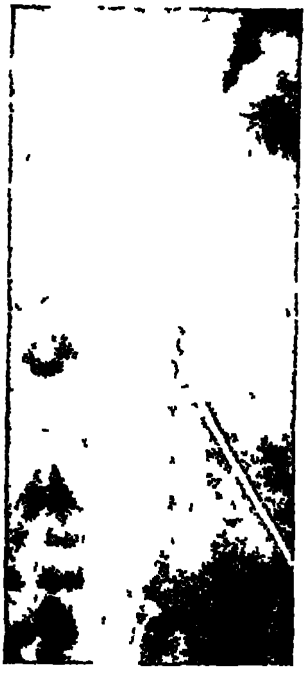

Fig 1—Lumbar aortogram *The needle has entered the sac of a dissecting aneurysm, which is shown extending up into the thorax Contrast medium has passed from the aneurysm into the true lumen of the aorta, which is shown lying parallel to the dissecting aneurysm and to its left*

This interesting finding raised the possibility that the hypertension might have been caused by the encroachment of the dissecting process upon the lumen of one or both the renal arteries Further investigation of the renal function showed that both kidneys seemed to function adequately It was thought, however, that if his blood-pressure could be reduced it would improve the long-term prognosis, and hypotensive therapy was therefore instituted

When seen in December, 1957, the patient remained well and free from fresh symptoms

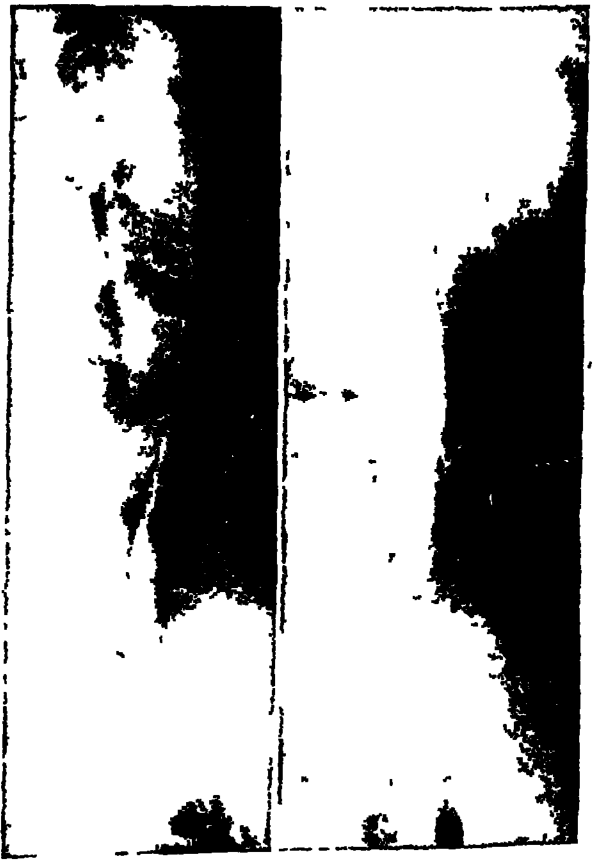
Discussion

The diagnosis of dissecting aneurysm, rarely made during life, may be suggested on a plain radiograph by progressive enlargement of the aortic shadow on serial films of the chest This possibility was raised in our patient on his original admission at University College Hospital However, this is a sign that must be treated with caution and can be misleading Great care must be taken that the serial films are exactly comparable One of us has seen a case where the diagnosis was confidently suggested on plain X-ray grounds, but not confirmed at necropsy The apparent mediastinal increase in width was then presumed to be largely artefact

The use of contrast media will allow positive proof of the diagnosis, but few previous cases can be found where these have been used In a case reported by Halliday (1952), a dissecting aneurysm was demonstrated by angiocardiography in the acute stage In another case of acute dissecting aneurysm (Warren et al 1956) a positive diagnosis was obtained by an aortic catheterisation in November, 1956

In our case a positive and unequivocal diagnosis was made by contrast vascular studies not only was the aneurysm itself directly demonstrated by lumbar aortography, but the original lumen of the aorta was clearly visualised by percutaneous catheterisation from the femoral artery

The angiographic findings in this case support the opinion of Drury (1955), who held that most of the patients who survive are those with a normal ascending aorta, and that most healed dissecting aneurysms begin at or near the aortic arch He was also of the opinion that the second factor that appeared to encourage healing was the length of the aneurysm Shennan's (1934) series was quoted to support the view that short dissections rupture early, and most healed dissecting aneurysms are long and sheath-like, extending from the arch to the iliac arteries He explains this by the hypothesis that the pressure within the aneurysm will equal that of the thoracic aorta at the point of primary tear from which it arises On the other hand, the pressure within the aorta will be lowered distally by successive branching A re-entrant tear will then be favoured by the resulting pressure difference which increases with the length of the



(a) (b)

Fig 2—Aortogram by femoral catheterisation *The true lumen of the aorta is demonstrated from the aortic arch down to the iliac arteries The aorta is displaced to the left and compressed by the dissecting aneurysm (a) as are the common iliac arteries (b) There was faint filling of the dissecting aneurysm from the true aortic lumen*

Serial films show the lower limit of the dissecting aneurysm to lie in the right common iliac artery The right renal artery was not demonstrated, and only a left nephrogram was obtained aneurysm Local factors in the structure of the distal aorta and the iliac arteries may also be important

Our case appears to support this concept The primary tear is thought to lie in the region of the aortic arch and the re-entrant tear in the common iliac arteries

Summary

A case of chronic dissecting aneurysm of the aorta complicated by hypertension is reported The diagnosis was made during life by lumbar aortography and confirmed by transfemoral aortic catheterisation

Our thanks are due to Prof M L Rosenheim, of University College Hospital, for permission to use the case-notes concerning the patient's first hospital admission in 1952

HYPOKALÆMIA FOLLOWING CHRONIC DIARRHŒA FROM OVERUSE OF CASCARA AND A DEFICIENT DIET

J D AITCHISON
M B Glasg, M R.C P, F R.F P S
ASSISTANT PHYSICIAN, WESTERN DISTRICT HOSPITAL, GLASGOW

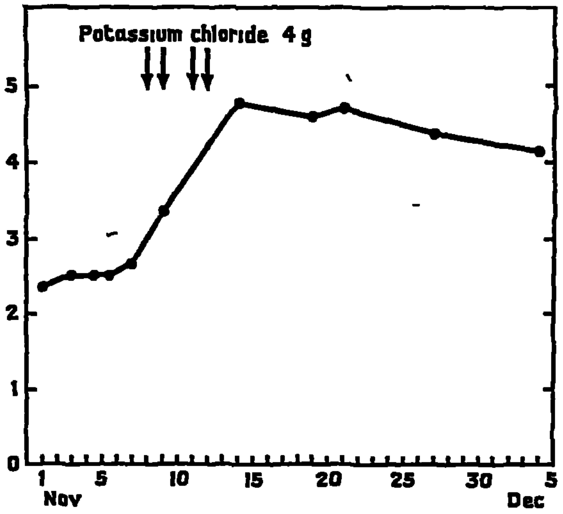
SEVERE potassium depletion and hypokalæmia following chronic diarrhœa induced by overuse of laxatives have been described in two otherwise healthy women by Schwartz and Relman (1953) In the case described here severe hypokalæmia developed in similar circumstances in a man aged 78 Associated muscular weakness of the limbs led to an initial diagnosis of cerebral thrombosis, but a routine electrocardiogram showed changes indicating hypokalæmia, which was confirmed biochemically

Case-report

A man, aged 78, came into hospital on Oct 27, 1956, because of sudden loss of power in his arms and left leg On the previous evening he had fallen asleep in a cinema and wakened with weakness of his limbs He made his way with difficulty to his lodging-house His doctor noted weakness of both arms and the left leg and sent him into hospital next day with a provisional diagnosis of cerebral thrombosis

On admission the patient still had marked weakness of his arms Abduction of his right arm and flexion of his left wrist and fingers were particularly affected His tendon-reflexes were depressed in the arms, particularly the left Power in his legs seemed, by this time, normal for one of his age and build. Next day, with no other treatment than rest in bed and an ordinary diet, he recovered power in his arms, and his tendon-reflexes returned to normal On Oct 30, 1956, routine electrocardiography showed changes indicating hypokalæmia The serum-potassium level was 2 3 mEq per litre The patient had not had any previous episodes of this kind, but he had had transient weakness of his fingers during the week before admission to hospital

Further observation showed that he was a depressed lonely old man He had retired from labouring nine years previously He had left his native Ireland as a young man and had no relations, and few friends in Scotland He felt unwanted and had the idea that the people in his lodging-house complained of an unpleasant smell emanating from him He thought this was the result of food rotting inside his body, and that it could be corrected by frequent aperients Consequently he had for months, if not years, taken two cascara tablets three times each day He was secretive and evasive about his bowel movements, particularly after he was forbidden laxatives, and refused to cooperate in the collection of specimens He regarded himself as constipated if he had fewer than three bowel movements in the day



Serum-potassium *levels, showing effect of increased intake of* potassium

Diet—He was vague about his dietary habits He had bought and prepared his own food for years and seemed to have lived for a considerable time on a diet consisting largely of bread, margarine, and tea He seldom, if ever, ate butcher's meat, bacon, or fish He may have had up to three eggs in a week He was 5 ft 8 in tall and weighed 7 st 10 lb when he came into hospital He was thin but showed no overt sign of malnutrition

Investigations—His urine was acid On repeated testing it was free from albumin, casts, and red cells and contained only an occasional leucocyte, it was sterile on culture on four occasions, its specific gravity was 1 008–1 012 The urinary excretion of potassium was 151 4 mg in twenty-four hours on Nov 7, 1956, and 72 8 mg on Nov 9 Potassium chloride 1 g four times daily by mouth was given from Nov 8 to Nov 12, and the urinary excretion of potassium in twenty-four hours was 222 5 mg on Nov 10, 363 mg on Nov 14, and 685 mg on Nov 15 The serum-potassium level was initially 2 3 mEq per litre and rose to the lower limit of normal after 5 g of potassium chloride had been given and remained normal thereafter The initial serum-bicarbonate level was 43 2 mEq per litre and the initial serum-chloride level 84 0 mEq per litre, but all the levels in the serum returned to normal and the electrocardiographic signs of hypokalæmia regressed as the serum-potassium level rose (see figure) On Nov 27, 1956, the specific gravity of the urine after fourteen hours' deprivation of fluid was 1 012, two hours after the ingestion of 1 litre of water it was 1 002, corresponding figures on Dec 6 were 1 018 and 1 001 Radiography of the chest, a barium meal, a barium enema, and intravenous pyelography showed no significant abnormality Fat balance was attempted but had to be abandoned because the patient resented being forbidden purgatives On Oct 30, 1956 the erythrocyte-sedimentation rate was 14 mm at the end of one hour (Westergren), the white cells numbered 8000 per c mm, Hb 11 9 g per 100 ml The Wassermann reaction of the blood was negative The fasting blood-sugar level was 90 mg per 100 ml The levels of acid and alkaline phosphatase, calcium, and inorganic phosphate in the serum were normal

Subsequent course—The patient's general health improved gradually, and after he had been six weeks in hospital he had gained $1^1/_2$ stone in weight Unfortunately, although his physical health was now quite satisfactory for a man of his years, his mental depression did not improve He was admitted to a mental hospital in May, 1957 He died suddenly, apparently of coronary thrombosis, two months later There was no necropsy

Discussion

In health potassium is excreted by the kidney and, to a lesser extent, by the bowel Depletion of potassium is usually the result of increased loss by one of these channels In the present case the urinary content of potassium, when first measured, was low The only abnormalities found in the urinary system were impairment of concentrating and diluting powers, which returned to normal after the potassium depletion had been treated A renal defect of this kind is known to result from potassium depletion (Milne et al 1957)

The bowel movements had been abnormally fluid and frequent for at least some months as a result of the daily ingestion of cascara The serum-potassium level was not measured until a few days after the transient episode of paralysis Probably the serum-potassium level was then even lower than the first, and lowest, recorded reading The serum-potassium levels rose again slightly without any other treatment than the withholding of laxatives and the giving of an adequate diet The administration of 5 g of potassium chloride brought the serum-potassium level to the lower limit of normal The total potassium supplement given was 16 g of potassium chloride Thereafter the serum-potassium level remained normal without any further potassium supplements No abnormality was found in the gastrointestinal tract, and normal bowel function was restored when laxatives were discontinued It is concluded that the potassium depletion and hypokalæmia with weakness of the limbs were due to increased fæcal excretion associated with a low intake of potassium

Summary

A case of hypokalæmia with severe muscular weakness of the limbs is described

The cause of the potassium depletion is thought to have been excessive use of cascara, causing chronic diarrhœa

The dietary intake of potassium was low

The hypokalæmia was diagnosed electrocardiographically

Preliminary Communication

AN ASSAY FOR INSULIN-LIKE ACTIVITY USING RAT ADIPOSE TISSUE

THE measurement of small amounts of insulin-like activity in blood and other biological fluids is still a problem A specific and sufficiently sensitive chemical, chromatographic, or immunological method, while highly desirable, is not yet available The assays so far developed are biological ones, based on insulin effects in vivo and in vitro—i e , on induced hypoglycæmia in rats and mice sensitised by endocrine manipulations,[1–3] on measurement of glucose uptake by the isolated rat hemidiaphragm,[4–6] or gas formation by mammary gland of the lactating rat [7] Because of the small maximal insulin effect (up to 2× baseline) the rat-hemidiaphragm technique demands extreme technical care if it is to achieve reproducibility and thereby adequate sensitivity Moreover, it requires the pooling of diaphragms of several animals for a given assay Hence, it has proved satisfactory in only a few laboratories

That insulin affects the metabolism of adipose tissue has been appreciated for some time,[8, 9] and more recently it has been recognised that this effect is direct, both in vivo [10] and in vitro [11]

In this laboratory [12] it has been found that insulin added in vitro to non-chilled, non-traumatised rat epididymal fat results in a fourfold increment in glucose uptake and an eightfold increase in the oxidation of glucose-1-^{14}C to $^{14}CO_2$ This observation has been adapted to measure insulin-like activity in biological fluids, and a technique has been developed [13] to measure quantities as small as 10 microunits per ml (01^{-5} or 0 00001 units per ml) Moreover, the epididymal adipose tissue from a given animal may be subdivided, giving 6 pieces (3 per side), thereby allowing comparison of insulin standards [14] and unknowns in tissue obtained *from the same animal*

PROCEDURE

Male albino rats of the Wistar strain are fed ad libitum and killed by a blow to the head and rapid exsanguination The epididymal adipose tissue is gently taken up at its base (just distal to the epididymal vessels), cut free (single cut), and, without manipulation or chilling, further cut into three equal pieces Each piece, weighing 80–200 mg , is dropped, as it is cut, into appropriate 10 ml rubber-stoppered flasks, preweighed, and containing 2 ml of plasma or Krebs bicarbonate buffer *containing gelatin 200 mg per 100 ml* and insulin in appropriate *dilutions The glucose concentration of both buffer* and plasma samples is made up to 300 mg per 100 ml containing 0 2 microcuries of glucose-1-^{14}C (1 9 ml buffer or plasma plus 0 1 ml glucose-1-^{14}C solution) The rubber stoppers are provided with two ports (glass tubing with rubber fittings) and with a small plastic cup suspended beneath one of these ports

After *reweighing, to obtain the tissue weight,* the flasks are gassed (using no 21 needles through the small rubber fittings) with 5% CO_2–95% O_2 for five minutes, the needles are withdrawn (leaving the system airtight), and the flasks are incubated for two hours at 37 6°C in a Dubnoff metabolic agitator at 72 cycles per min After incubation, using a tuberculin syringe and no 21 needle, 0 2 ml of NaOH *freshly diluted* 1 in 10 from saturated NaOH with CO_2-free water is introduced through the appropriate port into the suspended cup, and 0 2 ml 10 N H_2SO_4 is introduced into the medium After at least two hours, the contents of the suspended cup are transferred quantitatively to a weighed centrifuge tube containing $BaCl_2$, and the precipitated $BaCO_3$ is washed three times with CO_2-free water and *dried* and reweighed to give the total $BaCO_3$ *present* in the flask (usually 8–17 mg)

An aliquot of each sample is then transferred to a weighed planchette for determination of its specific activity in a proportional flow counter, giving counts ranging from several hundred to several thousand Results are expressed as counts per minute per total CO_2 (as $BaCO_3$) per 100 mg adipose tissue

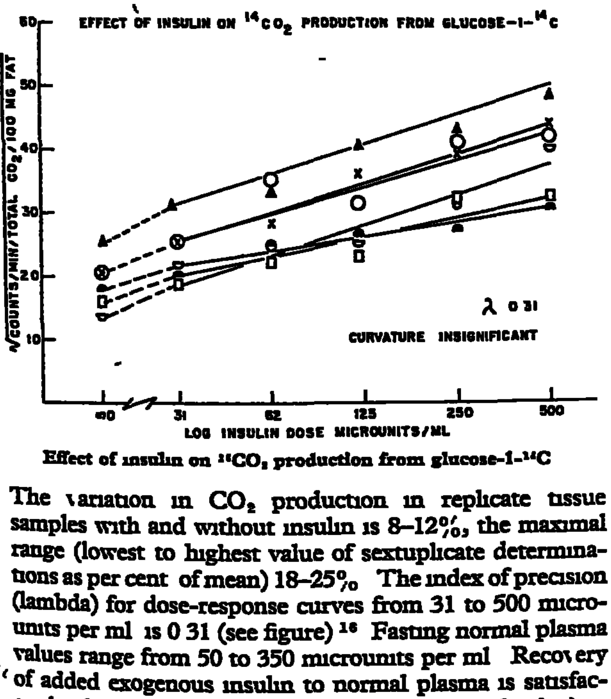
The modification using the glucose uptake as indication of insulin-like activity differs in that only 0 8 ml of buffer or plasma is used, the glucose concentration is 200 mg per 100 ml, the incubation period is four hours, and sample solutions of buffer and plasma without tissue are run concurrently Aliquots of 0 5 ml are taken after incubation and glucose determinations are carried out in duplicate according to Nelson.[15] Results are expressed as micromoles glucose "taken up" per gramme adipose tissue

EVALUATION

The method using CO_2 production from glucose-1-^{14}C is preferable There are only three critical determinations —tissue weights, total $BaCO_3$ weights, and specific activity It is feasible to carry 18 flasks (3 animals) through the procedure in one and a half days, and thus to compare in each animal 4 unknowns and 2 standards, allowing an unknown to be assayed simultaneously in 3 animals The limit of sensitivity is 10 microunits per ml (132% of baseline, S E ±4%, n=20, P less than 0 01)



Effect of insulin on $^{14}CO_2$ production from glucose-1-^{14}C

The variation in CO_2 production in replicate tissue samples with and without insulin is 8–12%, the maximal range (lowest to highest value of sextuplicate determinations as per cent of mean) 18–25% The index of precision (lambda) for dose-response curves from 31 to 500 microunits per ml is 0 31 (see figure)[16] Fasting normal plasma values range from 50 to 350 microunits per ml Recovery of added exogenous insulin to normal plasma is satisfactorily obtained (within 20–25% of the predicted value)

CONCLUSION

It would appear that the epididymal fat pad of the male rat can be successfully used for the assay of insulin-like activity in biological fluids This method, in our hands, has proven more sensitive, more convenient, and perhaps more accurate, than those previously described It is, however, only a measure of insulin-*like* activity, not of insulin *per se*, and more experience is needed for a fuller appreciation of its adaptability and limitations

Reviews of Books

Causes of Crime

Lord PAKENHAM London Weidenfeld & Nicolson 1958
Pp 197 21s

IN 1953 Lord Pakenham undertook a comprehensive inquiry into this subject at the instigation of the Nuffield Foundation it was interrupted after about a year by his public appointment, but he has now given us the fruits of his interim reflections He sets out the views of a galaxy of experts interviewed during the study, and digests the findings from a number of important British writings His conclusions are cogently argued and his opinions sound and sober, if not very controversial, and the book is easy and pleasant to read

The main theme is, inevitably, the morass of semi-knowledge wherein we flounder Lord Pakenham finds it easy to quote eminent authorities against each other on such basic points as, for example, the importance of intelligence or of mother's love Variations from place to place and from time to time make it very hard to assess statistically the recent supposed increase in crime, and international comparison is even less meaningful He points out correctly that the great majority of reasons put forward to explain this increase are, in reality, questions to which no answer yet exists unsubstantiated emotional views hold sway and facts are at a premium In his conclusions, however, he manages to avoid sinking into a paralysing "status agnosticus" He has a few suggestions to make about future research most are inevitably big undertakings and only a large well-endowed and, one might add, powerful institution could achieve them The need for the projected Institute of Criminology is inescapable and we must hope that Lord Pakenham's words will ring round the Palace of Westminster We recommend the book to a wide public, for, though it adds little itself, it could be the starting-point for many things

Die neuroallergischen Beziehungen in der Histopathologie der multiplen Sklerose

TIBOR LEHOCZKY, Hungarian Academy of Sciences, Budapest
Berlin Akademie 1957 Pp 176

Dr Lehoczky has made a thorough histological study of 20 cases of multiple sclerosis All were of the chronic progressive type, and 4 patients died during an acute exacerbation He emphasises the predilection for the optic system, and the frequency with which sclerotic foci arise under the ependyma of posterior and inferior horns, usually separated from the ventricle by a strip of intact tissue Acute inflammatory changes were found in most cases, mainly but not only in the periphery of foci The constant vascular changes (hyalinisation, delamination, œdematous filling of Virchow-Robin spaces, perivascular status spongiosus, stasis, and rarely thrombosis and the formation of microgranulomata—not only near the foci of sclerosis) are judged to be an essential part of the histological changes, and not secondary phenomena, thus, the disease involves the mesenchymal as well as the ectodermal component of the nervous system

The histological picture is compared with that of the virus forms of encephalitis and of experimental neuroallergic encephalopathy The important investigations in Russia by Margulis and his associates, who isolated three strains of virus from acute disseminated encephalomyelitis and found that the serum of patients with disseminated sclerosis could neutralise virus, are fully reviewed, but Dr Lehoczky failed to find in any of the reports of experimental infective encephalomyelitis a description of histological findings comparable with those in his human material On the other hand, the changes in the encephalitis induced by injections of brain emulsion with adjuvants, which was closely studied by Rivers, Ferraro, and others in the United States and by Lumsden in this country, closely resemble those of multiple sclerosis, and the encephalomyelitis which can follow rabies vaccination (described by Japanese workers) can be considered a link between the two diseases

---

[15] Nelson N *J biol Chem* 1944, 153, 375
[16] We are indebted to Dr Mindell L Sheps, assistant professor of biostatistics, Harvard Medical School, for help and advice

Dr Lehoczky attributes multiple sclerosis to a hyperergic antigen-antibody reaction in the nervous system—a similar view to that of McAlpine, Compston, and Lumsden He believes that the hypothesis of Lumsden (that the antigen-antibody reaction takes place on the surface of oligodendrocytes and the inhibition of an antienzyme results in hydrolysis of the lipids of myelin sheaths) is not yet established No attempt is made to reconcile the experiments of Margulis et al suggesting a virus ætiology with the histopathological and experimental evidence of an allergic process

Disinfectants

Their Values and Uses W E FINCH, of the disinfectants division, Prince Regent Laboratories, London London Chapman & Hall 1958 Pp 188 30*s*

MOST clinicians and many bacteriologists are confused by the range of chemical disinfectants now available Mr Finch's book may help them to appreciate the merits and limitations of the main classes and to use them to better advantage The coal-tar derivatives are helpfully discussed at some length, and the medical reader can learn the difference between black and white fluids—though he may be bored by the details of manufacture Quaternary ammonium compounds and hypochlorites are well discussed in separate chapters, but mercurials and dyes, still much used in hospitals, get only a few lines each

The chemical information is authoritative but much of the bacteriology is elementary (the glossary includes such terms as " gram-positive ", " aseptic conditions ", and " inoculate ") A chapter on methods of testing disinfectants would have been useful, there is some information about this but it is scattered through the book The importance of using neutralisers to inactivate disinfectant carried over during testing is implied but not specifically mentioned Five plates of general views in factories and a laboratory add to the cost of the book but not to its usefulness

Where Love Is

JOSEPHINE BALLS, children's visitor London Victor Gollancz 1958 Pp 224 16*s*

ALTHOUGH relatively few children are adopted, fostered, or taken into children's homes in this country each year, they are very important for two reasons First, the amount of care they receive is an index of the social conscience The spirit of Bumbledom is by no means dead, and shows itself in exactly the way that Dickens satirised " We must not be extravagant with the ratepayers' money " is the modern equivalent of " They always cost more to keep than they're worth ", and is found in the mouths of prosperous middle-class members of committees, which the 1948 Children's Act appointed to take the place of parents who, for good reasons or bad, have become unable to keep their children All children taken into care are " deprived " children Some of them have suffered severely, and it should be a criterion of civilised society to see that restitution is made to them The second reason is that a study of deprived children and their disabilities throws much light on the needs of children as a whole, and helps us to understand many disturbances of health and behaviour which would otherwise be obscure No general practitioner or pædiatrician can afford to ignore this subject

This book is not a treatise on the law and practice of the Children's Act it is a very readable account, by an experienced social worker (child care officer in the Children's Department of Northumberland), of the reasons which led her committee to use fostering rather than nurseries for the younger children in care Fostering is much less expensive than nursery care, but happily the decision was not made in a spirit of parsimony, but because of a recognition that nurseries, no matter how devoted their staff, simply cannot offer young children the intellectual and emotional stimulus and response which is a necessity for the development of personality and even of physical health

Everyone with experience of deprived children realises that prevention, not treatment, is the real answer Most deprived children are the neglected children of inadequate parents, themselves often " deprived " The final answer is therefore to be expressed in terms of education, premarital advice, and post-natal community support The more immediate answer is to give what help is possible to a family threatened with disruption, and, for this, new statutory powers are being sought to enable children's officers to act Family help service, organised by some local health authorities, is one method The causes of neglect or non-acceptance of children, however, are many and often hard to understand For a long time to come it will be necessary to " take children into care " Miss Balls' book gives an excellent introduction to the subject

Operative Surgery

Volumes 6 and 7 Editors CHARLES ROB, M C, M CHIR, F R C S, professor of surgery, St Mary's Hospital Medical School, London, RODNEY SMITH, M S, F R C S, surgeon, St George's Hospital, London London Butterworth 1958 Pp 273 110*s* each

ORTHOPÆDIC surgery is completed in the sixth volume with a section on operations on the hand and another on amputations Plastic surgery is then completely and adequately encompassed (the form of presentation, with its reliance on illustrations, is particularly apt for this subject), and gynæcology and obstetrics follow The seventh volume presents surgery of the breast very effectively (mammoplasty is considered here, rather than in the preceding volume) In the following section on genitourinary surgery, endoscopic appearances are successfully portrayed—an important feature in the description of operations such as transurethral resection

---

Modern Practice of Obstetrics (2nd ed London Baillière, Tindall, & Cox 1958 Pp 258 45*s*)—This edition of Mr D M Stern and Mr C W F Burnett's book appears six years after the first and, like its predecessor, provides brief didactic notes rather than detailed description or argument The chapter on antepartum hæmorrhage, for example, has been rewritten and now deals with the whole subject in 5 pages, which include an account of hypofibrinogenæmia The use of hypotensive drugs in pregnancy is outlined, but a critical evaluation of their usefulness would have been welcome The advances in obstetrics of the past few years are included Some lines of treatment now discredited might, with advantage, be omitted—for instance, the use of intrauterine pastes to induce therapeutic abortion and the recommendation of frequent feeds and sweetened drinks in the management of uterine inertia Today most authorities would regard both practices as potentially dangerous, though for different reasons, nor would they endorse the advice to leave a retained placenta, in the absence of hæmorrhage or infection, to be expelled spontaneously in the next few days It would be wrong, however, to underestimate, by criticising details, the value of a book with so wide a range, and many will find it a useful means of revision

Physics for the Anæsthetist (2nd ed Oxford Blackwell Scientific Publications 1958 Pp 443 60*s*)—Sir Robert Macintosh and his colleagues have always been active advocates of sound physical principles as the basis of good anæsthesia Indeed probably as much progress has stemmed from a rationalisation of the art of anæsthesia, and the consequent elimination of unscientific and undesirable techniques, as from the investigation and introduction of new drugs and methods Written to teach physics to practising anæsthetists, this book (shared with Sir Robert by Prof W W Mushin and Dr H G Epstein) makes the subject palatable, and the practical side is described and illustrated in a way that is entertaining and easily assimilated Moreover, scientific accuracy has not been sacrificed The first edition has been thoroughly revised and several additions have been made—notably, a chapter on pressure-reducing valves and four chapters on explosions, comprising nearly a third of the book That may seem a little out of proportion, but the subject of explosions, as it concerns the anæsthetist, has never been so comprehensively or authoritatively described This is an excellent book, well worth having and amply repaying repeated study

THE LANCET

Crime and Punishment

Lord **Pakenham**'s new book, *Causes of Crime* (reviewed on p 77), is a serious contribution to a serious subject He would be the last to claim that it is comprehensive, the gaps, particularly in foreign research, are too wide His advisers, however, must have helped him here, and the eclectic quality of the book does not detract from the value of its conclusions It is saddening to realise how elusive and contradictory is our knowledge of delinquency and crime, but the reader who is disappointed at his own imperfect understanding of the roots of crime can at least take some consolation from this book—at last he knows he does not know This reminder will do good provided it is a stimulus to renewed activity, and, although he does not discuss the matter, Lord **Pakenham**'s book is powerful ammunition for those striving for an Institute of Criminology Such an organisation would bring us into line with other countries, and, though valuable work is done at Cambridge, Oxford, the London School of Economics, the Maudsley Hospital, and elsewhere, an institute could undertake more comprehensive studies than are now possible Do approved schools, borstals, and detention centres work? Does one type of training give better results than another? Can potential delinquents be caught young, and, if so, can we abort their antisocial activity? There are half a hundred questions of great importance to which no satisfying answer exists and to which no answer is likely to be soon forthcoming Mr **Butler** seems more aware of this need than other Home Secretaries have been, but the limited expansion he has achieved at the Home Office is unlikely to meet it

The nature of the criminal act has long been the subject of bitter dispute, but, whatever may be the eternal truths underlying sin and crime, it is clear that "clinical" attitudes have slowly gained ground over the years Now it is not always just a question of quantifying the punishment to the crime Juvenile courts are taking the lead in recognising that some delinquents are disturbed rather than wicked children and need careful and individual consideration Few can doubt that a young child may reflect a disturbed home life in disturbed behaviour, one form of which may be delinquency, and most of us would surely wish to pity rather than punish this victim of evil circumstance But the delinquent child is father to the criminal man, and at what stage have we the right to change our attitude? More and more people realise that punishment per se is of less use to society and to the criminal than the creation of a person who is willing to help others instead of harming them To excuse punishment by saying it is a deterrent has a hollow ring to those acquainted with the opposition to the earliest reforms of the death penalty And to those who believe that the criminal act must ultimately come to be examined in its setting as a scientific problem of diagnosis and treatment (granting that the most effective treatment may sometimes be prison), Lord **Pakenham**'s views will be disappointing He believes that, for as far ahead as can be seen, conviction will be indissolubly connected with penalisation, and public opinion will not tolerate the idea of a penalty unrelated to the severity of the offence He holds, too, that to sever this relationship would be to "embark on a slippery slope" leading ultimately to the extermination of gypsies, Jews, Catholics, or others who may be accused of damaging the best interests of the State In company with Dr **Peter Scott**[1] and others, we look with misgiving at the proposal to incarcerate "psychopaths" up to the age of 25, even where no offence has been committed[2], but the recidivist criminal is another matter Almost any proposed reform is liable to draw criticism from somebody on the ground that it will open the way to terrible consequences But it is hard to see why, subject to rigorous safeguards, the "indeterminate sentence" should be any more a transgression against the freedom of the individual than the certification of the insane or defective is now—in fact it would probably be less so

In reality, of course, the indeterminate sentence is with us already—in the form in which it is applied to people who are found to be both criminal and insane It seems strange that a man who has repeatedly committed crimes of violence, only the thickness of the aorta maybe from murder, goes free at the end of his sentence, though every known prognostic index cries out that he will offend—and perhaps kill—again On the other hand, a patient who kills in a brief confusional or depressive psychosis is locked away for life, or at any rate for years after his recovery It is a solemn fact that men in the first group commit the spectacular murders that are in the headlines almost weekly, whereas Broadmoor patients who have been released have never killed again[3] Public opinion (that nebulous entity called upon to justify anything) may not be as averse as Lord **Pakenham** suggests to a form of indeterminate sentence

Œstrogen Measurement and Breast Cancer

Much effort is being applied to assessing and improving the effects on late breast cancer of œstrogen therapy Encouraging progress in the quantitative estimation of urinary œstrogens is referred to in the latest two annual reports of the British Empire Cancer Campaign[4] [5] and in the proceedings of a conference on endocrine aspects of breast cancer[6] Though at present we have to make do with excretion values, what we really want to know is the amounts secreted A step in this direction has been

6 Endrocrine Aspects of Breast Cancer (edited by A R Currie) Edinburgh, 1957

made by BROWN,[7] who injected known quantities of œstrone, 17β-œstradiol, and œstriol into four normal menstruating women and two men and estimated the moieties excreted in the urine The sum of these amounts was 16% of the total injected Assuming that œstrone and œstradiol or a mixture of both is the primary œstrogenic hormone in the menstrual cycle, BROWN suggests that the amount produced in the body in each twenty-four hours may be roughly estimated by multiplying the sum of œstrone, œstradiol, and œstriol excreted in that time by a factor of $^{100}/_{16}$ The result for the sample analysed was 4 8 mg during one menstrual cycle This method may provide a useful guide in substitution therapy But G F MARRIAN[6] has pointed out that present methods determine no more than 20–30% of œstrogen metabolites known to be present in urine (Do some also find their way into bile and become discharged through the bowel ?) In recent years four additional œstrogen metabolites have been found and characterised, and there are good grounds for believing that many more exist Another defect, to which attention is drawn by H BRAUNSBERG, A E KELLIE, J D N NABARRO, and D H PATEY,[4] is that estimations of œstrogens at low levels (3 μg or less) are inaccurate Available methods have been used largely to detect and measure œstrogen excretion after attempted total ablation of endogenous sources in the palliative treatment of late breast cancer The objectives have been to determine whether ablation has been complete, to correlate, if possible, the extent of fall in œstrogen excretion and clinical progress, and to obtain guidance on the most suitable form of palliation Moreover, quantitative data on œstrogen secretion in the long induction period of endogenous breast cancer will be needed in order to assess the part played by hormonal factors in causation Despite complete removal of known sources of endogenous œstrogens—the ovaries and adrenal glands—œstrogen is often found afterwards in the urine Accessory adrenals may persist, and other sources will have to be sought It is partly on account of the continued excretion of œstrone after these operations that hypophysectomy has been added to the surgical procedures, on the assumption that, as in the normal development of the breast both pituitary and ovarian hormones are required, so both sources may be needed for the growth of those breast carcinomas which respond to the absence of any one of them by temporary regression Professor ILLINGWORTH's team[4] report finding no correlation between clinical progress and the extent of the fall in œstrogen excretion after bilateral oöphorectomy and adrenalectomy, and N C SMITH, E BELL, and D LINDSAY[4] detected no œstrogens after the same operations in three-fifths of the patients in whom there was good clinical response

It is particularly difficult to account for the temporary recession of breast cancer in some postmenopausal women after administration of supplementary œstrogens If addition of these hormones is contemplated, measurement of the existing level of excretion might afford a means of predicting which patients will benefit and of determining the dose to be given A further problem exists in the reputed carcinogenic action of œstrogens By methods formerly used, no correlation was found between quantities of œstrogen excreted and established breast cancer, but such an association must be sought at a much earlier stage—perhaps for twenty years or longer This inquiry might be narrowed in two ways First, by concentrating on reputedly "precancerous" conditions, valuable information might be gained about the likely outcome of these states[8] Secondly, sufficient time has now elapsed since the introduction of synthetic œstrogens to look for evidence of any causal relationship with breast cancer P M F BISHOP and M MURRAY[4] have sought to record the results of treatment of 1029 patients for periods of at least six months Of these, only 530 could be traced and 2 only had developed cancer of target organs—in the uterus after eleven years, and in the breast after a few months' treatment with stilbœstrol (The breast tumour is unlikely to have been initiated, though it may have been promoted, by the œstrogen) A few other cases following œstrogen treatment have been recorded BUCALOSSI and VERONESI[8] recorded 2 among a group of 81 patients in whom a familial incidence had been established This observation suggests a further narrowing of the inquiry, and of œstrogen estimations, to females and males in whom a familial tendency is detected Farsighted provision for follow-up would be needed

It has long been known that the genesis of certain epithelial cytomas in animals is associated with naturally occurring or artificially altered hormone balances, and further that maintenance of the various growths of target cells depends on continuation of the same imbalance that brought them into existence Little quantitative work has been done, nor is it certainly known that these growths remain dependent once they have metastasised The exploration of this field, as was forecast by Dr CHARLES HUGGINS in his Macewen lecture in the University of Glasgow last month, may increase our understanding of many of these problems

Ventricular Septal Defect

VENTRICULAR septal defect in its typical form can usually be easily recognised, but the clinical picture varies considerably according to three principal factors —the size of the defect, the level of pulmonary vascular resistance, and the magnitude of the pulmonary blood-flow TAUSSIG[9] based her classification mainly on the site of the defect But subsequent studies suggest that it is the size of the defect rather than its position which largely determines the clinical picture, a small defect causes little hæmodynamic disturbance, whereas a large one produces large pulmonary blood-flows due to the left-to-right shunt, pulmonary arterial enlargement, and eventual heart-failure[10]

KIRKLIN et al[11] have given a detailed account of the site of defects of the ventricular septum based on 36 cases in which the defects were closed surgically. They classified defects into those related to the ventricular outflow tracts and those related to the inflow tracts. The former were subdivided into those inferior and those superior to the crista supraventricularis. The latter were divided into defects beneath the septal leaflet of the tricuspid valve and those near the apex of the muscular septum. The defects unrelated to ventricular outflow tracts were located entirely in the muscular wall of the septum, but those involving the outflow tracts (referred to as high defects), although often regarded as localised to the membranous septum, often involved a large area of muscular tissue adjacent to this region. The defects confined to the muscular septum were in the minority—11 of 38 defects in 36 patients.

The hallmark of the ventricular septal defect is the passage of blood from left ventricle to right ventricle—the left-to-right shunt. When the defect is small the shunt is small and symptoms are absent, the sole abnormal physical sign being the characteristic loud pansystolic murmur at the lower end of the left border of the sternum. There is no risk of heart-failure, and the sole hazard is that of bacterial endocarditis. With larger defects, symptoms of effort intolerance and respiratory infections are common, and growth may be retarded. The heart is enlarged, and death from heart-failure may result. Clinically, in such cases it is common to find hyperdynamic enlargement of the left ventricle, and to a lesser degree of the right. The characteristic loud pansystolic murmur is heard in the third and fourth interspaces at the left sternal border, an apical mid-diastolic murmur, due to increased flow through the mitral valve, is usually audible. The arterial pulse is small and slightly water-hammer in quality. The jugular venous pressure is normal unless heart-failure is present.[12] Radiologically the heart is considerably enlarged, with dilated pulmonary arteries and evidence of increased pulmonary blood-flow. The cardiogram shows greater hypertrophy of the left ventricle than of the right. Cardiac catheterisation reveals a large left-to-right shunt at ventricular level, normal arterial oxygen saturation, and normal, or near normal, pulmonary arterial pressure and resistance: the large pulmonary blood-flow is accommodated in the distensible pulmonary vascular bed without a rise in pressure. In some cases the Eisenmenger syndrome is present. This has been defined as pulmonary hypertension with high pulmonary vascular resistance and reversed shunt.[13] In such cases the left-to-right shunt is small or absent, a right-to-left shunt is present, and the clinical picture is one of extreme pulmonary hypertension with slight central cyanosis and clubbing. The mitral diastolic murmur disappears and the sound of the pulmonary valve closure is much increased. The cardiogram shows pure or dominant right ventricular hypertrophy, and the peripheral vascular markings in the lung may be reduced.[13 14] According to WOOD[13] the high vascular resistance is present from birth, and thus the clinical picture is entirely different from that of the large defect with left-to-right shunt and normal pulmonary vascular resistance. The right-to-left shunt in ventricular septal defect was originally attributed to overriding of the aorta, which received blood from the right ventricle. It is now considered that the right-to-left shunt results solely from increased pulmonary vascular resistance, which is at or near systemic level, when the aorta becomes "physiologically" overriding.[10 13] SELZER and LAQUEUR[15] suggested that there is no anatomical difference in the heart between uncomplicated ventricular septal defect and the Eisenmenger complex (better termed syndrome). The difference lies in the presence, in the latter condition, of reduced calibre of the pulmonary arterioles and consequent high vascular resistance. In any form of ventricular septal defect the aortic root may occupy its normal position, or may be overriding, or even partly or completely transposed.[15] Both WOOD[13] and SELZER and LAQUEUR[15] agree that the septal defect in the Eisenmenger syndrome measures 1 cm or more in diameter, which in the infant is of considerable size relative to the size of the heart.

A valuable study of the natural history of ventricular septal defect has been made by BROTMACHER and CAMPBELL,[16] who have analysed 75 cases. They classified these into five groups: small defects with small left-to-right shunt (3–3.5 litres per min), larger defects with a left-to-right shunt of 4–15 litres per min but with normal pulmonary-artery pressure, larger defects with considerable left-to-right shunts, and hyperkinetic pulmonary hypertension due to extreme flow rather than increased resistance, large defects with some increase in resistance but no reversal of shunt, and finally large defects with right-to-left shunt, in which the aorta is "functionally overriding." They regard the *maladie de Roger* and the Eisenmenger complex as the two extremes of a continuous series of cases of ventricular septal defect, and recommend that both eponymous terms be abandoned. Nearly three-quarters of their patients were under 20 years of age, and the sex distribution was equal, but the prognosis was considered to be worse in boys and men than in girls and women. BROTMACHER and CAMPBELL thought that the pulmonary vascular resistance tended to rise with age, in that the average age in the high-resistance cases was higher than that in the low-resistance cases. They consider that the pulmonary-artery pressure is usually high from birth, the hypertension at first is mainly hyperkinetic, but the resistance increases with age, as BLOUNT et al.[17] concluded. This is not in close harmony with WOOD's[13] view that the high vascular resistance is determined from birth. BROTMACHER and CAMPBELL[16] cite the case of a patient whose pulmonary vascular resistance was 8 units at the age of 5 years, and had risen to 23 units seven years later, but they do not believe that the pulmonary-artery pressure is likely to rise as a late complication in patients in whom it was initially normal. It may be, therefore, that the pulmonary vascular resistance is likely to rise with age only if it is initially increased These workers make valuable comments on lesions associated with ventricular septal defect Pulmonary regurgitation was diagnosed in 19 of the 75 patients, being nearly three times as common as in atrial septal defect The pulmonary pressure was increased in all save 1 Aortic regurgitation was present in 3 patients, 2 of whom died, and BROTMACHER and CAMPBELL regard this as a much more serious complication than pulmonary regurgitation The aortic arch was right-sided in 2 patients, and at least 3 had a left superior vena cava Changes of rhythm were uncommon, atrial fibrillation occurred in 1 man, and congenital heart-block in 1 woman, who was cyanotic The report refers briefly to 8 patients who were not included in the series because of a small pressure-gradient across the pulmonary valve, which was not attributed to pulmonary stenosis This "functional" gradient is now well recognised, as in atrial septal defect, in which the exact cause is not known [18]

The course and prognosis were analysed with reference to a further 100 patients who had not been investigated by cardiac catheterisation 11 patients died, 9 of them before the age of 25, 6 of these 9 died in childhood (1 at the age of 3 years), having enormous hearts, considerable left-to-right shunts, and heart-failure The tendency for patients with large left-to-right shunts to die in infancy is now established [19], and BONHAM-CARTER and WATERSTON [20] reported that two-thirds of a series of 200 patients with congenital heart-disease who died in infancy from acute cardiac illness did so under the age of 6 months Some of these patients presumably had ventricular septal defects, and it may well be argued that the principle mortality from this condition lies in the first year of life BROTMACHER and CAMPBELL [16] point out that if the patient survives infancy the prognosis is moderately good for fifteen years, but unless the shunt is small the outlook becomes progressively worse after this age, and few patients survive to 40 years A high infant mortality in ventricular septal defect would accord with WOOD'S [13] contention that patients in whom the high fœtal pulmonary-vascular resistance falls to normal soon after birth are in serious danger of death from heart-failure He goes further and suggests that in many cases the high pulmonary resistance of Eisenmenger's syndrome is life-saving, as it prevents the lungs being flooded with blood under systemic pressure and protects the left ventricle from the burden of the large left-to-right shunt The prognosis of the Eisenmenger complex is fair Of 35 fatal cases reported by SELZER and LAQUEUR,[15] 8 patients died in infancy, 4 between the ages of 3 and 10 years, and the remainder subsequently—1 patient living to the age of 60 19 patients survived to between the second and fourth decades, so there is a reasonable chance of a patient living to the age of 30, which agrees with BROTMACHER and CAMPBELL'S findings regarding ventricular septal defects of all types if the hazard of infancy is survived The high risk of infective endocarditis in ventricular septal defect is worth remembering it accounted for 28% of the deaths over the age of 1 year in SELZER'S [10] series, although it was not a prominent feature in the series of WOOD et al [13]

The surgical treatment of ventricular septal defect is now well established KIRKLIN et al [11] have reported excellent results in 36 cases, and the number is probably now much higher Closure requires the use of an extracorporeal circulation while the heart is opened and the defect closed, and the operation is therefore only possible in special centres. The indications for operation are a left-to-right shunt which is producing significant cardiac enlargement or effort intolerance, and early heart-failure Preferably the pulmonary pressure and resistance should be normal, but some hyperkinetic hypertension is no bar to operation, as the pressure will fall when the shunt is closed Since many patients probably die in infancy operation may prove to be most valuable when undertaken while the patient is in the first year of life The risks of operation are much greater when the pulmonary pressure and resistance are high and the shunt is reversed than in uncomplicated ventricular septal defect, and ZIMMERMAN et al [21] suggest that the pulmonary-artery pressure should ideally be below 75% of the systemic arterial pressure if closure is to be effected safely

Annotations

ASSESSMENT OF DISSEMINATED SCLEROSIS

DISSEMINATED sclerosis is diagnosed largely on the pattern of the disease in time and space But the characteristic picture of episodes of neurological dysfunction with partial or complete remission between—the episodes involving different areas of the nervous system or recurrent and increasing dysfunction of the same area—is by no means consistent A *spinal form* was early recognised as having a slowly progressive course without remissions and often without clear evidence of spatial dissemination In cerebral forms, too, an initial attack may be followed by steady deterioration In other cases a single attack is followed by complete and long-continued remission (even, occasionally, with no further recurrence) or by a series of attacks with complete remission between Other patients show increasing permanent disability after each attack In still other cases, perhaps the commonest, there is complete remission from each attack for a time and then a steadily progressive phase Examples of all these varieties have been confirmed at necropsy Thus if histological evidence of plaques of demyelinisation with profuse astrocyte infiltration and characteristic relation to blood-vessels and grey matter is accepted as pathognomonic of disseminated sclerosis, such patients must be regarded as having that disease After the first five years *all forms of the disease show* a tendency to become steadily progressive, and there is some evidence that, apart from the variations already mentioned, in general the disease may take either a relatively benign or an inexorably progressive form

These features make diagnosis and prognosis difficult and the assessment of treatment even more so If any remedy were truly curative, this could *hardly escape* detection, but if the effect were simply to slow down or modify the disease process, this would be less easily appreciated Conversely with treatment instituted around the fifth year apparent benefit might really be due to natural decline in relapses and remissions as the disease enters a chronic progressive phase

[18] McDonald, L *Brit Heart J* 1958 20, 268
[19] Marquis, R M *ibid* 1950, 12, 265
[20] Bonham-Carter, R E, Waterston, D *ibid* 1958, 19, 589
[21] Zimmerman H A, Kay, E B, MacKrell, J, Sambhi, H P *Amer Heart J* 1957, 54, 727

Experience with the various remedies has illustrated these difficulties Of the older remedies arsenic is still advocated despite the occasional tragedy of arsenical epitheliomas Administered for periods of years, it is claimed to bring about cessation of relapses, but in many cases, however treated, relapses cease after five years Fever and shock therapies are less popular now, anticoagulants, anti-histamines, and low-fat diets, although not widely accepted, have their adherents

In this situation the carefully matched control series may be particularly helpful The recent report of Alexander et al[1] from Boston is therefore welcome They studied a group of 554 patients with disseminated sclerosis over an eight-year period and confirmed that the peak incidence is in the third decade, the disease being largely confined to the 20–40 age-group, that the frequency is greater in women than in men, that the disease tends to become less active after the first five years, and that there are probably two groups—a mild and a severe The particular merit of this report is its emphasis on the need for a quantitative estimate of disability and for assessing treatment against a control series matched not only for age, sex, length of illness, and condition at the start of treatment but also for quantitative illness record for a year before treatment Four treatments were thus investigated vitamins plus muscle adenylic acid, blood-transfusions, corticotrophin, and cortisone Of these, transfusions appeared to aid in resolution of attacks, while corticotrophin aided resolution and both prevented and reduced frequency and severity of subsequent attacks and reduced progressive disability between attacks The others had no significant effect The claim, which contrasts with the admittedly less extensive experience of other workers, that corticotrophin beneficially affects all aspects of the disease process will certainly lead to further clinical trials Let us hope these also will be so controlled that the results are meaningful

COMPLEMENT AND STIMULANT

THE Nuffield Provincial Hospitals Trust was founded in 1939 with the main purpose of coordinating hospitals and ancillary medical services on a regional basis This objective was largely fulfilled with the start of the National Health Service, but in the second decade of its short life the Trust has done work no less valuable than in the first decade

Coordination is still the principal aim, and this is reflected in the financing by the Trust of the development of group-practice and clinic centres at Harlow As a large voluntary agency, the Trust complements and stimulates official action by discovering facts on which official policy may be based, and by encouraging the practice of promising but unproved ideas In these ways such a body as the Trust can go far towards preventing the conservatism and rigidity often seen in activities paid for from Exchequer funds A report on the work in the past three years[2] remarks sensibly "that a trust must be careful not to duplicate work best done by public authorities Above all, it has a duty to be far thinking and try to interpret its objectives in relation to the requirements of the times Its policy, if not opportunist, must be as flexible as its trust deed permits " How well this Trust is succeeding is evident from the list of projects, established and new, that have gained its support

The trustees are continuing to support an exhaustive study of the administration of the National Health Service, which is being published by the Acton Society Trust New projects under organisation include further studies of hospital case-loads, to provide a basis for planning, follow-up studies of the working capacity and needs of patients discharged from hospital, and an investigation into the use of health and social services Of special interest and importance is a grant to help in planning to bring into use the new Princess Margaret Hospital at Swindon A working party is studying all aspects of the operation and will record its findings for the benefit of any hospital authority that has a similar, sadly unfamiliar, duty Many further projects sponsored or supported by the Trust are listed under organisation and the further headings of mental health services, care of the aged, rehabilitation services, general practice, industrial health, training and education, and design and operation

BRONCHOGRAPHY IN PULMONARY TUBERCULOSIS

VARIOUS workers, notably Dormer et al,[1] have studied the use of bronchography in pulmonary tuberculosis, but until recently the method was little applied in this condition, partly owing to the danger of extending the disease, and partly because residual unabsorbed oil obscured further radiographs Chemotherapy and the introduction of a new contrast medium, propyliodone ('Dionosil') have changed all that Except in patients with a persistently positive sputum due to drug-resistant organisms, the risk of the disease being spread after adequate chemotherapy has practically vanished, and the contrast medium disappears promptly from the lung fields, furthermore because, in the new medium, iodine is in organic combination, the rare tragedy due to iodine-sensitivity is no longer liable to occur

The routine use of bronchography in cases of pulmonary tuberculosis where surgery is contemplated has also been favoured by the increasing recognition of the limitations of the ordinary radiograph While these limitations are in some degree overcome by tomography—lateral sections are particularly helpful—the bronchi themselves can be properly delineated only by a contrast medium, and the importance of the bronchus as a factor in the physiopathology of pulmonary tuberculosis is now more fully appreciated Furthermore the tendency is to resort less often to bronchoscopy, partly because lesions in the major bronchi are known to heal readily with chemotherapy, partly because the lesser bronchi cannot be seen, but principally because bronchography is such an efficient method of "lung-mapping" that in most cases bronchoscopy is unnecessary Bronchography is less upsetting than bronchoscopy with local anæsthesia, and general anæsthesia is necessary only in young children The contrast medium itself is relatively non-irritating, although a mild febrile reaction may ensue

Most thoracic surgeons contemplating resection for pulmonary tuberculosis now routinely request pre-operative bronchography, it is of value sometimes in the investigation of "round shadows" which may be

[1] Alexander L. Berkeley, A W, Alexander, A M. *J Amer med Ass* 1958 166, 1943

[2] The Nuffield Provincial Hospitals Trust a record of the progress of schemes and descriptions of new projects 1955–58 Issued by the Trust, Nuffield Lodge Regents Park, London, N W 1

[1] Dormer B A, Friedlander, J, Wiles F J *Amer Rev Tuberc* 1944, 50, 283, 287, *ibid* 1945, 51, 62, 455, 519

either tuberculous or malignant, as with the latter a distant "block" may be apparent, and anatomical variations from the normal bronchial pattern can be demonstrated preoperatively Merrill and Sampson,[2] analysing a series of bronchograms of their tuberculous patients in 1956 at the Highland-Alamida Hospital, Oakland, California, point out that pathological examination of resection specimens has contributed to diagnostic accuracy and that changes in the segmental bronchi are comparable with those in the major bronchi They are, however, critical of the view which accepts the mere presence of ectatic bronchi as an indication for resection, resected specimens of these bronchi are not uncommonly smooth-walled and non-caseous, which would seem to indicate that little harm would have resulted if the decision had been against operation As the effectiveness of properly managed long-term chemotherapy becomes ever more evident, the indications for operation are becoming fewer and less clear-cut The presence of distinct stenosis may indicate the need for surgical intervention, as in the "middle-lobe" syndrome or where an empyema space communicates with the bronchus But there is still a real need for accurate assessment of the results of long-term chemotherapy, and we cannot yet prognosticate clearly from the bronchographic picture regarding patients with ectatic bronchi in whom control appears to have been achieved by chemotherapy There is of course some risk of secondary infection, though it does not seem to be great, of hæmorrhage, though this is apparently unusual, and of recrudescence of disease, though this depends also on other factors such as the presence of cavities, round foci, and apical deposits, besides general factors, including inherited resistance and constancy and duration of chemotherapy

CANCER CONGRESS

SOME 2500 members and associates from more than sixty countries enrolled for the seventh International Cancer Congress, held in London this week under the presidency of Sir Stanford Cade, who read a message from the Queen, the congress patron The congress was opened on Monday by the Duke of Gloucester, and the meetings, of which we hope to give some account, were continuing until Friday

TREATMENT OF TROPICAL EOSINOPHILIA

THE syndrome of tropical eosinophilia (pulmonary eosinophilia, eosinophilic lung) is familiar to practitioners in Asia The patient is an Indian with paroxysms of coughing specially at night, added sounds on chest auscultation, significant eosinophilia, and increased shadows in the chest radiograph The cause is unknown, but arsenical treatment is usually successful Other features, which are variable, include asthma, chest pain, scanty hæmoptysis, insomnia, fatigue, weight loss, and—specially in children—enlarged lymph-glands and liver Fever is usually slight or absent, but the erythrocyte-sedimentation rate is increased The onset is typically insidious and the illness continues with remissions for weeks, months, or years—up to twenty years has been recorded[3] There are a host of causes and degrees of eosinophilia in the Tropics, but many clinicians regard tropical eosinophilia as a clear-cut entity On the other hand, Aitken and Roy,[4] in their study of 200 cases on a Bengal tea estate, found that the symptoms were protean, and the majority had no symptoms at all Gelfand[5] encountered similar cases in Rhodesia Aitken and Roy suggested that hospitals saw selected examples of a syndrome which was confined neither to the Tropics nor to the lungs, and suggested the term "eosinophilic syndrome group"

In treatment organic arsenicals, which are usually effective, may have to be given for six to eight weeks The main drawback is toxicity—especially arsenic encephalopathy, which is often fatal Such an outcome is particularly unfortunate in an illness which is not fatal in itself Danaraj[6] considers that toxic reactions are commoner than published reports would indicate He therefore studied the effects of other empirical measures, including antibiotics, sulphonamides, bismuth, cortisone, piperazine, and diethylcarbamazine Only diethylcarbamazine produced results comparable to those of arsenic Diethylcarbamazine was advocated by Friess et al,[7] who found *Wuchereria malayi* in lymph-nodes of six soldiers returning from Indo-China with tropical eosinophilia, and earlier reports of the use of this drug were favourable[8-11] In Singapore Danaraj[6] has studied the effects of diethylcarbamazine in 110 patients of whom 90% were male, over 80% adult (in other series, children and females have predominated), and over 70% Indian—although Indians form only 7 8% of the population of Singapore Selection criteria were an eosinophil-count of over 3000 per c mm, increased shadows in the radiographs, an erythrocyte-sedimentation rate of more than 10 mm in the first hour, and no evidence of past or present filarial infection Dosage was 4 mg per kg thrice daily for four days in 46 cases, and 6 mg and 10 mg per kg body-weight thrice daily for five days in 57 and 7 cases respectively The patients were observed, mostly as out-patients, for an average period of six months Symptoms improved within two to four days of treatment being started, but the response was better with the two larger dosages than with 4 mg per kg Giddiness and frequent vomiting occurred in 6 of the 7 patients given the 10 mg per kg dose, and Danaraj therefore recommends 6 mg per kg body-weight thrice daily for five days as the standard dosage Eosinophils fell to below 3000 per c mm in five to thirty days according to the initial level The chest radiograph cleared more slowly, and the erythrocyte-sedimentation rate was still increased in 25 patients at the end of the period of observation Only 1 patient—1 of 17 Chinese—showed no response 3 patients had relapses

These results are very encouraging, particularly as diethylcarbamazine is relatively non-toxic The results would have been even more convincing if a double-blind controlled trial had been carried out As the syndrome is relatively common in India and Malaya, such a trial should be readily feasible Last year Gault and Webb[12] reported finding nematode larvæ in the liver of a patient with tropical eosinophilia, but full understanding of the cause—if in fact there is a single cause—continues to elude us[13] Why is the syndrome in Malaya virtually confined to Indians? Does a genetic or dietary factor make the Indian more susceptible to a parasitic infection? Why is the cough so persistent at night? Lung biopsy at night might reveal the answer

TEN YEARS' GROWTH OF THE WORLD HEALTH ORGANISATION

H. S. GEAR
M.D., B.Sc. W'srand, D.P.H., D.T.M. & H.
From the World Health Organisation, Geneva

IT is interesting to recall the mood of 1945 and 1946 which led to the launching of the United Nations Organisation and some of its specialised agencies.[1] The world, reacting to the misery and disturbance of the war, was ready for, indeed expecting, concerted action to give all peoples fuller and better lives. The emergence of the atom bomb and the talk then of fearsome biological warfare also impelled a search for closer international cooperation in resolving quarrels and removing their causes. The widespread prevalence of want and disease were believed to be prominent among such causes. Hence the urgency to extend international association in functional fields as well as in those of traditional diplomacy.

As regards health, this mood simplified the acceptance of principles long advocated:

1. A single international body to coordinate health affairs.
2. Membership to be universal.
3. Functions to be comprehensive—i.e., not limited to quarantine and similar traditional functions.

Now that ten years have passed since the first World Health Assembly met in Geneva in July, 1948, examination of the application of these principles should be instructive.

Membership

During that first Assembly of the World Health Organisation, the ratifications of the constitution brought the membership of Governments to 55. Further ratifications and the accession of new countries have now increased the membership of W.H.O. to 85 members and three associate members. The only intergovernmental agencies with more comprehensive membership are the Universal Postal Union (96) and the International Telecommunications Union (91).

In 1949 and 1950 the Governments of Soviet Russia, the Ukraine Republic, Byelorussia, Bulgaria, Rumania, Albania, Czechoslovakia, Hungary, and Poland, informed the Organisation that they no longer considered themselves members of the Organisation, but, as the constitution makes no provision for withdrawal, they were regarded as "inactive". In the year ending last January the Soviet Union, Poland, Czechoslovakia, Bulgaria, Albania, and Rumania, resumed active membership.

Structure

Ten years ago there were a headquarters in the Palais des Nations at Geneva, a liaison office in the United Nations headquarters in New York, and an epidemiological quarantine office, taken over from the League of Nations, in Singapore.

Despite some initial doubts about the wisdom of its early application, the principle of regionalisation was put into effect immediately. The world was divided into six regions, and by 1951 regional organisations were operating in all. These now have headquarters as follows:

African Region	Brazzaville
Region of the Americas	Washington, D.C.
South-East Asia Region	New Delhi
Eastern Mediterranean Region	Alexandria
European Region	Copenhagen
Western Pacific Region	Manila

The Americas had long had their own regional health body in the Pan-American Sanitary Organisation, with its bureau headquarters in Washington. By an agreement of 1949 the P.A.S.B. assumed its role of the regional office of W.H.O. Each of the regional offices has grown with the years and now keeps in close contact with the health authorities of its region.

The trend of decentralisation has not stopped with the establishment of the six comprehensive regional offices, each operating with its appropriate regional committee of local Governmental representatives. A varied system of subdivisions has appeared.

In the African Region there are four areas under the supervision of public-health officers.

Even before the advent of W.H.O. the Region of the Americas had zone offices in Guatemala City and Lima. It now has six zones, each with its own headquarters.

In the South-East Asia Region there are five area representatives stationed in Burma, Ceylon, India, Indonesia, and Thailand.

The European Regional Office has not yet any geographical subdivisions. In 1956 the Eastern Mediterranean Office appointed four public-health advisers to coordinate the programmes in Libya, Saudi Arabia, and Yemen, Ethiopia, Sudan, and Somalia, Iran, Iraq, and Pakistan, and Jordan, Lebanon, and Syria. In view of the present suitability of this arrangement, a scheme for area representatives has not yet been put into force. Area representatives have, however, recently been appointed for three groups of countries, and a fourth is to be added soon in the Western Pacific Region.

Thus ten years' growth has led to a large, even complex, system of regionalisation, with subdivisions undertaking the general programme and administrative functions of the Organisation in the individual countries of the world.

A Decade of Programmes

The programmes fall into three broad groups, though in practice these have not always remained distinct.

(1) *General Technical Services*

The general technical services are given to the world as a whole. These are the traditional services which countries have found it essential to seek from an international body. They arose to meet the need for common understanding and action on the terminology and classification of the causes of mortality and morbidity, on the description of drugs and related substances, on the definition of the agents and causes of diseases, microorganisms, &c., and on the quarantine procedures acceptable for international traffic.

This traditional work has been maintained and extended by W.H.O. The International Lists of Diseases, Injuries and Causes of Death have twice been revised under its ægis. These are now being applied by many more countries in a continuing effort to produce fuller and more accurate records of both mortality and morbidity, without which health and medical programmes are liable to be aimless and wasteful. This basic statistical work has contributed much in all regions to preliminary programmes of world epidemiology. Epidemiology, in the full modern sense of the word—a study of factors influencing the health of a community—has emerged as an essential responsibility of W.H.O. Statistical data are but part of the epidemiological information needed on world and regional conditions. In such subjects as malaria, tuberculosis, poliomyelitis and the other virus diseases, "cancer", circulatory conditions, accidents, and mental disease much additional epidemiological work has been done. In most cases the prosaic but essential preliminaries have first been taken nomenclatures and classifications have been prepared, arrangements have been made for reference material, bacterial types, &c , to be distributed, and basic clinical, pathological, and therapeutic definitions have been reached Thus the way has been prepared in many countries for the application of modern measures The common understanding now being found in these basic statistical and epidemiological criteria has also meant an expansion in both the number of subjects and the geographical areas in which investigation is proceeding as a cooperative arrangement The work on malaria, bilharziasis, and enteric infections are examples of how world cooperation in research has been much helped by the agreements on nomenclature, reference material, and technical descriptions sponsored by W H O

---

[1] Gear, H. S. *Brit. med. J.* 1956, ii, 471.

Another example of general action is in the health procedures for international traffic The last few years have seen significant reductions both in the prevalence of the so-called quarantinable diseases and in the oppressive and obstructive measures previously applied to shipping, aircraft, passengers, and goods in order to prevent their spread We now know more about the epidemiology of cholera, smallpox, plague, typhus, and yellow fever, and the argument that barriers are effective against them—quarantine inspection, holding of ships and aircraft, quarantining of passengers—is less often used We now believe that quarantine systems have played a relatively small part in reducing their world importance local measures taken by individual countries—e g , better water-supplies, disposal of waste products, cleaner towns and ports, and ships properly constructed and kept free from rats, &c —have been usually more effective This refreshing change in attitude has enabled the old Sanitary Conventions, so hampering to world movement, to be superseded by the much less restrictive International Sanitary Regulations of 1952[2] To resist cholera, plague, and the rest, countries increasingly depend on their own internal sanitary condition rather than on the doubtful defence of quarantine

Another action taken through W H O which has had both medical and economic advantages has concerned the international and local use of drugs, antibiotics, and the like In most countries the practitioner and the pharmacist use drugs—diagnostics, prophylactics, and therapeutics—which have been manufactured in other countries, and there is obvious need for generally intelligible and acceptable dosage standards governing potency, purity, and safety Early efforts made by the League of Nations have been carried forward, often with the assistance of W H O , and recommendations are made, for example, in the *International Pharmacopœia*[3] A list of international non-proprietary names is helping to decrease the confusion caused by the labels—often different in different countries—given to new medicinal substances It has helped manufacturers as well as doctors

The international work on biological standardisation, also initiated by the League of Nations Health Organisation, has been much accelerated by W H O By 1945, when W H O took on this work, thirty-four international biological standards—in such substances as digitalis, vitamins, antitoxins, and antisera—had been established In the past ten years another fifty have been prepared This again assists the manufacturers and distributors as well as the users of these substances The international standards are held, on behalf of W H O , in the Statens Seruminstitut, Copenhagen, and the National Institute for Medical Research, London

(2) *Education, Training, and Technical Information*

Several allied programmes may be described together in this group Governments have sought much guidance and help in the fields of medical education and technical information Indeed, in a sense, all services provided by W H O for its member countries have had, as a main objective, education and the diffusion of information

Countries eager to develop their own medical schools, and to provide themselves with the advantage of modern medicine and public health, have made use both of the W H O fellowship system (for training their own people) and of the arrangements for obtaining advice from experts who may visit them individually or in groups The fellowship programme—much indebted to earlier international schemes, including those of the Rockefeller Foundation—has been prominent among W H O activities throughout the decade

In *1947–56* 6396 fellowships were granted to people from 149 countries and territories These fellows went to 113 other countries to receive training—almost always postgraduate The subjects studied were health services by 59%, control of communicable diseases by 28%, and medical education, clinical science, and other subjects by *13%* of the fellows

The fact that W H O fellowships are now being used each year by nearly 1000 medical and allied people makes this one of the most significant postgraduate training schemes ever developed Countries are thus getting knowledge and skill to guide their own advances A large number of training institutes (universities, medical schools, research laboratories) receiving W H O fellows have become partners in the diffusion of experience and information

This movement of fellows, and the reverse flow of teachers and consultants, in so many countries and territories, must have effects beyond the specific training for which they were designed Their influence in drawing at least medical and technical communities of the world together, in creating common traditions and associations, and in giving common standards, practices, and languages, will probably continue to radiate good will and community of purpose for many years after the actual exchanges

It is too trite to claim again the value of publications in diffusing scientific and technical knowledge A whole series has been developed by W H O for its international purposes

Most originated in the League of Nations Health Organisation or in the *Office International d'Hygiene Publique* These have been issued in terms of the publication policy laid down by the Health Assembly and the Executive Board, which requires material to be selected for publication which has a direct relation to international medicine or health Thus the quarterly *W H O Bulletin*, its principal scientific journal, has included articles on laboratory studies on communicable diseases, control of disease, geographical distribution of disease, surveys of regional or world health and medical subjects, and reports of W H O field projects

Epidemiological and statistical data have been presented in monthly and annual reports to furnish essential material for research-workers and medical administrators everywhere Over thirty years of reports now make a valuable repository of world medical and health facts, incomplete and uneven in quality though the material still is The issue of summaries of national health legislation has been a routine practice for several decades, appealing mainly to certain official groups The introduction in 1952 of comparative surveys of legislation on such subjects as smallpox vaccination, nursing, leprosy, malaria, and midwives has enlarged the usefulness of the publication in question, *The International Digest of National Legislation* It has become a ready reference for medical administrators, practitioners, and others concerned in keeping the legislation of their own countries adapted to modern technical and administrative requirements

---

[2] Gear H S , Deutschmann Z *Chron World Hlth Org* 1956, 10, 273

[3] Pharmacopœia Internationalis Geneva, 1951

W H O technical publications—one, the *Chronicle*, in the five official languages (Chinese, English, French, Russian, and Spanish) and others in English, French, and Spanish—help scientific and technical institutions and people throughout many countries to keep in touch with subjects of importance to international health They offer accessible guidance and reference to many medical and health groups concerned in international programmes and services So far, they have been carefully directed to be complementary to, and not in competition with, the well-known medical and health journals of international appeal published in a number of countries

(3) *Country Project Work*

This third group of activities has been the most prominent in the first ten years of W H O It became so to meet insistent demands from its member Governments for advice and help in creating new, or expanding existing, country health and medical services These requests have varied from a simple need for a visiting consultant (to advise a country for a few days on a single subject) to a complex agreement between W H O and associated international agencies to help a country over a period of years in establishing a whole health department or such a special service as tuberculosis control or a new medical teaching faculty This has been the type of service most enlarged by all international agencies in recent years It has been the main activity not only of the United Nations family of specialised agencies but also of vast programmes conducted under the aegis of the Colombo Plan, and the various bilateral arrangements sponsored by the United States of America In the case of W H O, this form of direct assistance to individual countries making requests has grown substantially In 1949 the direct expenditure on such advisory services was 2,199,456 dollars In 1957 it was 12,024,699 dollars—by far the largest item of expenditure

This form of aid to Governments is popular It is so in all W H O Regions and in all medical and health fields—clinical, preventive, and investigational Through it and the allied bilateral programmes (Colombo Plan, T C A, &c) the last ten years have witnessed the rudiments of health and medical services growing in practically all countries Modern scientific medicine, through general practitioners and hospital, through training institutions, and in many cases through special services to deal with malaria, yaws, and the like, has been extended into the most primitive communities It was to meet a fundamental principle that the advisory services given by W H O have been directed towards strengthening the local national and local services and not towards creation of new institutions and departments detached from the local political and administrative systems The aim has been to induce self-help, adjusting aid from outside to internal conditions, customs, and needs [1]

Expenditure

Expenditure is an obvious index to programme and administrative change year by year But the annual expenditure is not always a complete reflection of trends, because it is affected by such factors as changes in the value of currency, special non-recurring commitments, and emergencies

The annual financial reports of W H O reveal an uninterrupted increase in expenditure for the decade The first full programme year, 1949, showed an expenditure of 6,005,629 dollars, and the most recent, 1957, an expenditure of 17,681,877 dollars In other words, in the ten-year period the costs of the programme and administration have roughly trebled

The expenditure has been met by income from several sources, but most of these have been relatively minor Most of the regular annual income has come from the member States directly These contributions from Governments, according to an agreed scale of assessments, rose from 3,693,603 dollars in 1949 to 11,517,988 dollars in 1957

The annual expenditure in 1957 has been classified as follows

	(*Dollars*)
Organisational meetings	373,361
Operating programme	15,925,260
Administrative Services	1,383,256
Total	17,681,877

In the first year, 1948, about 66% of the assessments were collected in the year, but since 1951 the collections have been 90% in each year, and for 1957 the proportion was over 97% This is practical evidence of vigorous participation by Governments in the work of the Organisation, without which there would be uncertainty, confusion, and haphazard effort

The programmes of the Organisation have also benefited much from the contributions made by two funds the United Nations Expanded Programme of Technical Assistance for Economic Development of Under-developed Countries, and the United Nations International Children's Fund (UNICEF) In each country with a W H O project there has been counterpart expenditure to pay for the local personnel, transport, supplies, &c, necessary to complete or continue the new or improved service

Staff

The World Health Organisation took over a staff of 206 from the interim commission which had continued essential work and plans in the period between the International Health Conference 1946 and the first World Health Assembly in 1948 Many of these had previously worked in the earlier health bodies of the League of Nations, &c Ten years later, in 1958, the staff numbers 1481, distributed as follows

Headquarters and attached offices	501
Regional offices	459
Area and zones offices	38
Field staff (in projects in countries)	483
Total	1481

The staff now includes nationals of 53 of the 88 member States, and members of most branches of the medical, public-health, and nursing professions Many other members of these groups have worked for the Organisation in various ways during the decade The large number of technical meetings sponsored by W H O have drawn in temporarily from a number of countries many hundreds of clinicians, technical officers, scientists, and administrators There has been almost a constant flow of short-term consultants on behalf of W H O to assist a varied programme of projects in countries, and of plans and reports in headquarters and the regional offices Such officers are not regular staff members, but leave the health services, hospitals, and universities of their own country for temporary duty with W H O Some features of this type of arrangement have been discussed earlier [1]

General Remarks

Inheriting much goodwill, experience, and resources from previous international bodies, the World Health Organisation was designed to coordinate intergovernmental health and medical work and to cooperate with other similar international agencies both governmental and non-governmental It has proceeded far in this role Financial support has been continuous and general Participation of many interests, governmental and non-governmental, in its programmes has been keen, and the granting of resources to it has been generous Countries are using both its general world-wide technical services (epidemiological, statistical, quarantine, standardisation, drugs, &c) and its direct aid in the local development of medical and health services It has become a comprehensive organisation with a fully developed regional system. It is now a means of associating services, institutions, and individual workers in a wide variety of medical and health programmes

In terms of international arrangements, ten years is a short period, and no attempt has yet been made at detailed analysis and evaluation of the results of the work of W H O But the growing demand for the services, as shown by the growth of its expenditure, is an index of its present popularity

THE TENTH ANNIVERSARY

LAST Saturday the Minister of Health, Mr DEREK WALKER-SMITH, Q C, sent the following message to the various authorities responsible for the operation of the National Health Service in England and Wales

> Ten years ago a beginning was made with a quite new venture in the field of social welfare—the organised provision of a comprehensive health service for everybody, and today the National Health Service completes ten years' work
>
> They have been years not free from difficulty There have of course been many problems—problems of new patterns of administration, problems arising out of the nation's economic circumstances, and the multifarious problems of growth and development in new directions to meet changing needs But these ten years have been years of solid achievement, and I feel that it would be wrong to let this anniversary pass without seeking to convey to you and all engaged in the National Health Service and in the associated welfare services the sense of gratitude and appreciation so widely felt throughout the country
>
> We recognise most easily and acknowledge most readily our debt to the skill and care of doctor and dentist, pharmacist and optician, nurse and midwife, health visitor and home help, physiotherapist and radiographer, and all those many others who are in immediate contact with the individual person and his needs But there are many more whose contribution may be less apparent but is no less real I have in mind, for example, hospital domestic, kitchen, and laundry staff, maintenance workers, ambulance staff, porters, laboratory technicians, those caring for old people and for the handicapped, administrative and clerical staff, and all who, often unseen and sometimes unrecognised, by their work enable expert care to be brought more quickly and more adequately to the help of the patient
>
> I have also specially in mind the continuing and generous contribution, made not only by those whose daily work lies in the health and welfare services but by the thousands of men and women who render voluntary service of every kind It is a remarkable and encouraging feature of the past ten years that the provision of comprehensive health services by public authorities out of public funds has not resulted in any falling off in voluntary work but rather in a renewal and a resurgence of it in new and varied forms Not least remarkable and encouraging—and this is characteristic of the whole health service—has been the constant willingness of volunteers to devote their time and energies to public service as members of the authorities responsible for the local administration of the different branches of the National Health Service, thus continuing and reinforcing the tradition which has long been a distinguishing feature of administration in this country A great and often unacknowledged debt is due to authorities like your own for their work not only in promoting the public good generally, but also in ensuring that health services shall be preserved as personal services meeting the needs of individual human beings
>
> Ten years is a short period in the life of these services, and we must look ahead as well as back, deriving encouragement from the success so far won to help us in meeting the changes and chances of the future I am confident that your authority and all who are engaged in the health and welfare services will mark the tenth anniversary in this spirit, and will go forward with renewed vigour and purpose

Public Health

ARSENIURETTED HYDROGEN POISONING IN TANK CLEANERS

A T DOIG
M D St And, F R F P S, M R C P E, F R S E, D P H

ARSENIURETTED hydrogen (arsine) is an extremely toxic gas which can produce a serious illness mainly due to rapid hæmolysis Because cases of poisoning by it are comparatively rare, many doctors are unfamiliar with its action Therefore, despite the striking and rather characteristic syndrome, the diagnosis may easily be missed

I call attention here to the main features of poisoning by arseniuretted hydrogen, mention the principal occupations in which the risk is present, and describe three cases which occurred in the cleaning out of acid tanks This occupation is comparatively seldom mentioned in the literature as giving rise to cases, and is one which, though common in chemical works, is often regarded as devoid of danger

Arseniuretted hydrogen is produced whenever nascent hydrogen comes into contact with a soluble arsenical compound It was identified and described by Scheele in 1775 It is colourless, inflammable, and unstable, depositing arsenic on exposure to light and moisture. It decomposes on being heated to 230°C Its vapour density is 2 68 times that of air It is a strong reducing agent Textbooks of chemistry describe it as having an unpleasant smell like garlic, but this cannot be relied on in concentrations met with in industry, and most victims are unaware of any unusual odour

Occurrence and Incidence

Certain derivatives of arseniuretted hydrogen, such as lewisite (chlorovinyl-dichlorarsine), are used in chemical warfare Apart from the manufacture of these compounds arsine is little used in industrial processes, but its evolution from dissolved arsenical material in the presence of nascent hydrogen is used as a test for minute traces of arsenic, as in the well-known Marsh's, Fleitmann's, and Gutzeit's tests

Arsenic is a very common contaminant of metallic ores and is therefore frequently present in various commercial grades of metals, such as zinc, iron, copper, and tin It is present in iron pyrites and so finds its way into commercial sulphuric acid made from pyrites and into hydrochloric and other acids made from sulphuric acid The evolution of arseniuretted hydrogen may therefore be an accidental and undesired accompaniment of many industrial processes, and especially

NOTIFIED CASES OF ARSINE POISONING AND OF TOXIC JAUNDICE, 1945–56

Year	Arsine	All cases of toxic jaundice
1956	1	2
1955	—	—
1954	2	2
1953	—	—
1952	6 (2)	6 (2)
1951	2 (1)	3 (1)
1950	—	—
1949	2 (1)	2 (1)
1948	—	4 (1)
1947	—	—
1946	—	1
1945	—	6 (1)*

Numerals in parentheses indicate numbers of deaths

* H.M Chief Inspector of Factories in his annual Report for 1945 shows 2 deaths due to toxic jaundice in that year, but 1 of these had been previously notified in 1944

in conditions of poor ventilation may constitute an unexpected danger Arsenides are often present in furnace residues derived from metal smelting and purification, and the accidental wetting of these—e g , by rain water—has caused fatal cases of arsine poisoning

Poisoning has occurred in many industries, particularly in the smelting and refining of many metals, including gold, silver, steel, lead, zinc, tin, and aluminium, and in chemical works, as in the manufacture of acids, sulphates, and chlorides, and in galvanising, dyeing, paper manufacture, fertiliser manufacture, electroplating, and others The manufacture of a solution of zinc chloride for use as a flux in soldering, sometimes done by workmen by the rough-and-ready method of " killing " commercial hydrochloric acid with a piece of scrap zinc, may give rise to dangerous amounts of arseniuretted hydrogen Several professional chemists have been affected in the course of their laboratory work Dimethylarsine is well known as having been the cause of many fatal cases of poisoning in residents of damp houses, it was liberated from Scheele's green, a wallpaper pigment no longer used as such in this country, by the action of a mould

It seems likely that most cases which are recognised are notified to the Factory Inspectorate, because, apart from certain research departments and laboratories not under the Factories Acts, exposure to arsine would most often take place on factory premises Cases are usually notified either as " toxic jaundice " or as gassing accidents, but they could conceivably be notified as toxic anæmia or even as arsenical poisoning During the twelve years 1945–56 13 cases, 4 of them fatal, of poisoning by arseniuretted hydrogen came to the notice of the British Factory Department (H M Chief Inspector of Factories 1945–56) The accompanying table shows the distribution by years and, for comparison, the total number of notified cases of toxic jaundice due to all causes, including arseniuretted hydrogen

This table brings out the important role of arseniuretted hydrogen in causing toxic jaundice in peacetime, because if we exclude 1945 (when all 6 cases were due to trinitrotoluene), 13 of 20 cases were due to arseniuretted hydrogen in 1946–56, and 13 out of 15 cases in 1949–56 The causes of the 26 cases of toxic jaundice were as follows

Arseniuretted hydrogen	13 (4)
Trinitrotoluene	6 (1)
Carbon tetrachloride	2
Chlorinated naphthalene	1
Paint-remover	1 (1)
Other	3

Numerals in parentheses indicate numbers of deaths

The occupations of the 13 persons who were poisoned by arseniuretted hydrogen were as follows

Tin smelting, handling arsenical dross	6 (2)
Cleaning sulphuric acid tanks	3 (1)
Laboratory workers	2
Cleaning reaction in vessel which had contained arsenic acid	1(1)
Mixing oxalic acid and other chemicals in vessel contaminated with As O,	1

Numerals in parentheses indicate numbers of deaths

The 13 cases occurred in seven incidents, all 6 tin-smelters being affected in one and both laboratory workers in another An excellent account of the 6 cases in the tin-smelters is given by Macaulay and Stanley (1956)

Symptoms and Diagnosis

Arseniuretted hydrogen is one of the most toxic gases known Concentrations of 3–10 p p m will produce slight symptoms after several hours' exposure, and concentrations of 16–30 p p m are dangerous after $^1/_2$–1 hour The maximum allowable concentration recommended by the International Labour Office for an 8-hour working day and the " threshold limit value " adopted by the American Conference of Governmental Industrial Hygienists, 1957, are 0 05 p p m (compared, for example, with 100 p p m for carbon monoxide) Repeated exposure to low concentrations may have a cumulative effect

Two simple chemical tests are available for detecting small concentrations of arseniuretted hydrogen, one using silver-nitrate papers and the other mercuric-chloride papers The Department of Scientific and Industrial Research (1940) describes a quantitative test

After exposure to toxic concentrations of arseniuretted hydrogen there is usually a delay of 2–24 hours before the onset of symptoms When arseniuretted hydrogen enters the blood-stream it combines with the hæmoglobin and hæmolyses the red blood-cells The first symptoms are usually vague malaise, nausea, giddiness, and headache, rapidly progressing to severe illness with vomiting, intense headache, pains in the loins, and the passage of dark urine (hæmoglobinuria) The progress of hæmolysis rapidly causes profound anæmia The liver and kidney functions are severely disturbed and usually break down in the effort to eliminate the products of the disintegrated corpuscles Jaundice is usually evident on the 2nd or 3rd day and increases to an intense coppery hue There is oliguria with albumin, casts, hæmoglobin, and methæmoglobin, and in severe cases there is suppression of urine Œdema of the lungs, with accompanying cyanosis, is a common complication, and in fatal cases there is usually delirium followed by coma

It will be appreciated from this description and the three illustrative case-reports below that a sudden onset of severe illness with gastric upset and the passage of urine the colour of port-wine in an industrial worker or chemist is sufficient to direct suspicion to the possibility of poisoning by arseniuretted hydrogen Rapidly developing jaundice, anæmia, and evidence of kidney damage greatly strengthen the suspicion Inquiry should be made about the patient's occupation, particularly the precise work on which he was engaged during the previous 24 or 36 hours The whole working-time should be accounted for because exposure may have been limited to a few minutes The diagnosis is clinched by obtaining a history of exposure or by finding arsenic in the urine, because during the acute stage and for some weeks afterwards arsenic is excreted by the kidneys

In making a retrospective diagnosis after recovery in patients where the correct ætiology was missed during the acute stage, examination of the hair and nails may reveal arsenic In this connection the method of activation analysis of tissues described by Dewar and Lenihan (1956) deserves mention This very sensitive method depends on the induction and subsequent measurement of radioactivity in the sample by treatment in a nuclear reactor It enables very small amounts of tissue to be analysed, and abnormal amounts of arsenic may be found in a single hair

Prognosis and Treatment

Prognosis turns largely on the state of the kidneys and is generally related to the amount of urine passed the smaller the amount the graver is the case Death usually takes place between the 4th and 10th days Kober and Hayhurst (1924) give the fatality-rate of recorded cases as 25–30% They suggest that this may be artificially high because fatal cases tend to be recorded more than recoveries Locket et al (1952) cite mortality-rates of 20–31% Hunter (1955) refers to 7 deaths in 25 cases (28%) in tin-refining In the 13 cases referred to above it is 31%

The danger being usually intermittent and fortuitous, the patient is rarely actually exposed to the gas when symptoms develop If he becomes ill while at work he must immediately be withdrawn from exposure, and any contaminated clothing must be removed Early removal of the patient to hospital is essential, and general measures should be instituted forthwith to deal with pain and anxiety and to minimise shock Early deaths are often due to pulmonary œdema When this is present, oxygen, preferably under pressure, probably offers most hope of averting death

High hopes that dimercaprol would prove of value have not been sustained, it has been used in most of the recently published cases, but the results have been far from convincing, even when the dosage was adequate Locket et al (1952) say that, although it is of doubtful value, dimercaprol should be given if the patient is seen within the first 24 hours, after that it is more likely to add to his burden

Dextrose and saline solution given intravenously with calcium gluconate has been advocated, but the daily fluid intake must be kept low in anuria and severe oliguria and the volume and composition of the body fluids as nearly normal as possible Hyperpotassæmia must be guarded against

Most workers advocate transfusion, preferably with packed cells, but Locket et al say a transfusion should only be given if there is severe anæmia McKinstry and Hickes (1957) say that if they see a patient with symptoms of severe poisoning, they intend to begin massive exchange transfusion as soon as the diagnosis is made, thereby helping to reduce the amount of arsenic and arsenical compounds in the blood and to get rid of reduced hæmoglobin and cellular debris and so to lessen or to prevent the blockage of the renal tubules

Cases in Tank Cleaners

The three cases briefly described here occurred at different times in different chemical works, but all were in men who had entered tanks, which had contained sulphuric acid, to clean them All the tanks had held acid made from iron pyrites—in two cases exclusively, in the third, a tank used for transport of acid by rail, oleum (fuming sulphuric acid), made by burning sulphur, had also been carried occasionally

The arsenic content of sulphuric acid made from pyrites varies a good deal but, calculated as As_2O_3, is usually about 0 2–0 3% and may sometimes be more Glaister (1908) cites arsenic contents of commercial sulphuric acid up to 0 15% and for hydrochloric acid as much as 0 691% Since the tanks were lined with lead, it was expected that the deposit would be almost entirely composed of lead sulphate Analysis of part of the deposit concerned in case 2 below, however, showed that it contained 45 0% by weight of As_2O_3, and a later sample from another tank contained 18 6% It seems that the arsenic impurities in sulphuric acid tend to settle out on standing Glaister (1908) quotes Cameron as having reported in 1856 that about 1 oz of crystallised arsenious acid was deposited after long standing from 8 lb of sulphuric acid

When the deposit is not very hard it can be removed by directing a strong jet of water on to it from outside the tank When it is hard, the tank has to be entered and the deposit removed by hand with such tools as a scraper and a shovel Cleaning may be required at intervals of 6–12 months, and the method of hosing, followed if necessary by entry, has been used for years Chemists, managers, and workmen do not appear to have anticipated the presence of any dangerous gas, and no special precautions, such as the use of breathing-apparatus, have in the past been taken in the three factories concerned Suitable protective clothing was, of course, provided and worn According to the size of the tank whether it contained internal baffle plates or not, the hardness of the deposit, and other factors, the cleaning of one tank might take a few hours or a few days

Case 1—A man, aged 52, was certified as having died of hæmolytic anæmia Death was not definitely attributed to occupation, and no suggestion was made that arsine might have been the cause The occurrence came to my notice several months after death, and on inquiry the typical story of poisoning due to arseniuretted hydrogen came to light

Exposure and onset—The man had been employed for some years at a factory where sulphuric acid was manufactured from iron pyrites by the chamber process On a Saturday morning he entered a stock tank, which had contained concentrated sulphuric acid, to clean it He was in the tank for about half a hour, from 8 30 to 9 A M He finished his shift as usual at noon and went home He became ill about 5 30 P M on that day with colic, abdominal pain, and vomiting Next day he was admitted to hospital, where he died on the 6th day of the illness

On admission he was much jaundiced and anuric 2 oz of urine the colour of port-wine was obtained on each of the following 2 days, and thereafter he was anuric until death His urine contained hæmoglobin and methæmoglobin His blood hæmoglobin was 81% on admission but on the day preceding death had decreased to 45% and the red cells to 2,760,000 per c mm No hæmolysins were found in his blood Treatment was by intravenous drip with glucose

Necropsy findings—The lungs showed severe hæmorrhagic œdema, with many hæmosiderin-laden phagocytes in the alveoli The liver was slightly enlarged, rather pale, and soft, but without fatty degeneration or necrosis, the centres of its lobules showed a good deal of pyknosis of the liver-cells The kidneys showed severe hæmoglobinuric nephrosis, almost all the collecting tubules containing precipitated hæmoglobin or acid hæmatin The loops of Henle and the distal convoluted tubules contained many casts The glomeruli were practically normal The cause of death was acute hæmolytic anæmia and renal failure

Case 2—A man, aged 34, had been a chemical-works labourer for more than 5 years and had cleaned many acid tanks in that time Before his illness he and his usual mate had been engaged in cleaning a rail-car tank which had been used for many years for transporting sulphuric acid It was 15 ft long by 5 ft in diameter, and had one man-hole, the interior was divided into three compartments by two baffle-plates, each with a man-hole The tank had usually carried concentrated pyrites acid but in recent months had contained oleum at times The deposit was very hard and could not be dislodged after flooding and hosing The men took it in turns to enter the tank for spells of about ½ hour each. On the Friday, when work started, and on the following Monday each man probably spent 2–2½ hours inside the tank, on the Saturday morning about 1 hour each, and on the Tuesday about 1½ hours each before noon, when the work was completed. About 2½ tons of deposit was removed. The mate was unaffected, but the patient became ill early on Tuesday evening with nausea, abdominal pain, and headache, which later became severe and were accompanied by vomiting.

On admission to hospital next morning he had hæmoglobinuria and was icteric. Examination of his blood showed hæmoglobin 80%, red cells 4,400,000 per c.mm., and white cells 14,000 per c.mm. Serological tests for Weil's disease were negative. The man made an excellent recovery without any specific treatment, and no transfusions were required.

Laboratory tests.—Analysis of two types of pyrites acid which had been carried in this tank car showed an arsenic content, expressed as total As, of 0.27% and 0.36%. The arsenic content of a sample of oleum was 0.01%. The men had used a steel scraper, an iron shovel, and a galvanised iron bucket in the tank. Laboratory tests with the deposit showed that arseniuretted hydrogen was generated from it by using zinc, and traces by using mild steel. A quantitative analysis of part of the deposit removed last during cleaning showed the astonishing figure of 45.0% arsenic calculated as As_2O_3.

Case 3.—A man, aged 35, was notified as having toxic jaundice of unknown origin, the notification being received after his recovery. Though it was suspected that his illness might have had an occupational cause, the possibility that this might be arseniuretted hydrogen had not been considered, and the mangement and staff of the factory were unaware that this hazard existed in the works.

Exposure and onset.—On the day his illness started, the patient had entered an acid-storage tank to clean it. The tank measured 6 ft. high by 9 ft. in diameter and had held concentrated oil of vitriol (98% sulphuric acid) *made from pyrites.* After washing out the tank several times with a hose he had entered it, taking a copper shovel and a galvanised pail with him. He spent two or three periods of ½ hour each in the tank. When he returned home in the evening he felt tired and was unusually thirsty but had no appetite. Severe headache developed, and during the night he vomited and passed urine which he described as nearly black.

On admission to hospital next day he was extremely ill and jaundiced, and his urine contained methæmoglobin and albumin. Liver-function tests showed some liver damage.

Treatment and progress.—He was treated with intravenous methylene-blue and ascorbic acid and with cortisone 200 mg. daily during the acute stage. In addition he had a high-carbohydrate low-fat diet. He made a full recovery. His hæmoglobin decreased to 40%, but at the time of discharge was 95%. Normal liver and kidney functions were entirely regained, and 2 weeks after his discharge his serum-bilirubin was 0.4 mg. per 100 ml., his hæmoglobin was 100%, his urine was normal except for excess urobilinogen, and he looked and felt well.

Laboratory tests.—Specimens of his hair and nails were obtained 10 weeks after the onset and subjected to analysis for arsenic content by the activation technique. The specimen of hair was reported as containing 7.6 p.p.m. of arsenic and the nails 4 p.p.m., both values being rather high. The tests, repeated after 4 months, showed the arsenic content of the hair as 1.5 p.p.m., which is within normal limits, but the content of the nails was still rather high at 6 p.p.m.

Prevention

Undoubtedly the most important factor in prevention is a knowledge of the risk. The three cases described occurred because the danger was not appreciated, and it seems incomprehensible that the managements of the three factories did not foresee the risk of generation of arseniuretted hydrogen during the work of cleaning the tanks. The cases occurred in 1949, 1951, and 1956, and obviously there had been little or no interchange of information between the factories nor effective publication in the chemical trade journals, and the references to the cases in the annual reports of H.M. Chief Inspector of Factories had been missed. It is to be hoped that a knowledge of this serious danger will soon permeate to the staffs of all factories where acid tanks may have to be cleaned, and from them to the workmen who have to do the job.

So far as possible, acid tanks should be cleaned without entry. When the deposit is soft, this can usually be done by repeatedly flushing with water and draining. When the deposit is hard, softening might be effected by strong alkalis or by steam. According to the nature and construction of the tank, in some cases it might be possible to bore or cut a hole or holes in the bottom or sides to allow of the insertion and manipulation of scraping tools. When the tanks are entirely composed of sheet lead, this would not offer much difficulty. It might be possible to prevent the deposit from becoming very hard by arranging for regular cleaning at relatively short intervals.

Proper equipment for the job should include protective clothing consisting of acid-resisting suits, head covering, and rubber boots and gloves, and non-metallic tools, such as scrapers, shovels, and buckets. Breathing-apparatus should be worn if entry is necessary, the most convenient type probably being an air-line mask enabling the worker to breathe fresh air through a flexible hose extending to the open air outside the tank. A mate should always be immediately at hand outside, and, where the entrance to the tank is small, or where there are interior baffle-plates which might hamper rescue in an emergency, it is probably wise for the worker entering to wear a safety belt, the attached rope being held by his mate outside.

Legal requirements are quite definite about precautions which have to be taken when work is done inside enclosed spaces where dangerous fumes are liable to be present. They are laid down in section 27 of the Factories Act, 1937, modified by section 11(2) of the Act of 1948. In factories to which the Chemical Works Regulations, 1922, apply Regulations 6–9 are particularly relevant to the work in question and must be observed.

Discussion

Poisoning by arseniuretted hydrogen produces a serious illness with a striking clinical picture. The dominant features are acute hæmolysis and jaundice, and perfectly correct diagnoses, such as acute hæmolytic anæmia, hæmolytic jaundice, and toxic jaundice, are easily made on the clinical findings. The true ætiology, however, is often overlooked. In two of the three cases described (cases 1 and 3) the possibility that arseniuretted hydrogen might be the cause does not appear to have been considered until investigations were made some time after the illnesses, although certainly in case 3 an industrial cause was suspected. Case 2 was correctly diagnosed by the general practitioner as arsine poisoning; he had, by an extraordinary coincidence, attended case 1 about 18 months previously and instantly recognised the typical syndrome.

The reason why the ætiology is missed is of course the rarity of the condition. Very few physicians in general or in hospital practice ever have an opportunity of seeing a case. It should, however, be noted that arseniuretted hydrogen is one of the commonest causes of industrial toxic jaundice in peacetime, when trinitrotoluene is not being manufactured on a large scale

The ignorance of chemists and plant managers about this grave risk seems to me much more remarkable It is a well-known fact that acid made from pyrites contains arsenic as an impurity, and the presence of arsenical compounds in the deposit in tanks which have contained commercial sulphuric or hydrochloric acids should be appreciated and the danger of evolution of arsine recognised In none of the three factories concerned with these cases was entry into acid tanks for cleaning considered to carry any risk of exposure to dangerous gases, and such entry had taken place on several occasions without special precautions having been taken So far as is known, no harmful effects had followed these previous entries Even after the occurrence of cases 1 and 3 the managements and technical staffs were unable to pinpoint the hazard At the factory where case 2 occurred, however, the origin of the gas was recognised when the correct diagnosis of poisoning by arseniuretted hydrogen was known, and the works chemist demonstrated its evolution from the deposit from the tank with iron and zinc, the metals of the shovel and galvanised bucket used

It is quite probable that unrecognised cases of arsine poisoning have occurred in the past from the cleaning of acid tanks when less thought was given to possible occupational causes of illness than today The extreme toxicity of the gas makes it essential that works managers, chemists, and foremen in factories where sulphuric acid is stored in tanks should show a much greater awareness of this grave danger than they have shown in the past

It seems too that a reminder to the medical profession would not be out of place, for, although poisoning with the gas usually produces a very characteristic syndrome, it is one which few physicians have an opportunity of seeing, and the diagnosis, or at least the ætiology, is thus easily missed

It is worth emphasising too that H M Factory Inspector should be notified immediately the cause of the illness is ascertained or, even better, as soon as an industrial cause is suspected If this were done, an immediate investigation would be made at the factory Since the cleaning of one tank may take several days, as in case 2, early notification—for example by telephone—of one case may lead to the institution of suitable preventive measures before a second case results H M Medical Inspectors of Factories will be ready to give assistance in regard to diagnosis and investigation

Summary

Poisoning by arseniuretted hydrogen, though relatively rare, is one of the commonest causes of toxic jaundice in peacetime In spite of the typical syndrome cases may be missed

The risk of poisoning by arseniuretted hydrogen in cleaning tanks which have been used for storing or transporting strong acids does not appear to be fully appreciated Three cases arising from cleaning sulphuric-acid tanks are described, one of them fatal

This danger should be made widely known among technical staff of factories where strong acids are stored Doctors and factory managers should realise the importance of early notification of cases to the Factory Inspectorate

I received a great deal of help and information from managers, chemists, and other staff of the factories where the three cases occurred and from general and hospital practitioners who attended the affected men I thank them all, and Dr Colin Campbell for information about the necropsy findings in case 1, and Dr J M A Lenihan for the activation analyses on material from case 3

Points of View

EVOLUTION AND ILLNESS*

R M J HARPER
M A, D M Oxon
PHYSICIAN, NORTH DEVON INFIRMARY, BARNSTAPLE

> " What do these rudiments, these apparent imperfections mean? There must be some cause for them, they must be the necessary results of some great natural law "—A R WALLACE (1855)
>
> " It is a relief to have some feasible explanation of the various facts, which can be given up as soon as any better hypothesis is found "—CHARLES DARWIN to A R WALLACE (1868)

A FRESH field of clinical investigation opened when it was recognised that certain primary disturbances of the human mind can damage *distant and diverse* structures throughout the body Doctors working within the complex environment of modern society are re-examining some aspects of disease that they believe to be related to such factors as the growing complexity of life and the closer impact of parents on their smaller families There is a desire to contain the vagaries of stress-conditioned illness within the bounds of a rational physiology, and an increasing recognition that the *anatomical* distribution of the consequent organ damage is often influenced by the genetic constitution of the patient, of his family, and of his race

In the wild state of Nature, we understand something of the basic laws of selection acting on gene-conditioned variations in plants and animals In agricultural and horticultural selection we see at work the minds of men, seeking to improve their stock by the conscious application of skilled experience In man, since he became human, unique forces, still largely veiled in mystery, have acted to condition his fitness for selection, and to produce, partly by the greater relative safety of a civilised environment, certain modifications of behaviour and of structure Yet all this great advance has been achieved with the maintenance of—and (some believe) partly because of—the very generalised human anatomical form Man reveals an "astonishing conservatism of anatomical structures as the result of which their traces may still be detected millions of years after they have ceased to have any function" (Le Gros Clark 1950)

---

* The text of the essay from which this article has been condensed can be obtained from the author

Commonly found on human skin are structures which, judging by their anatomy and histology, are significant ancestral characters dating to man's early mammalian and amphibian-reptilian evolution In the past a study of these structures, which were regarded merely as "beauty-spots" or "birthmarks", would have seemed irrelevant to clinical medicine But their identification as evolutionary vestiges (de Cholnoky 1939, Laidlaw and Murray 1933, Stout 1948) adds a new interest to the study of the supernumerary nipple and the pigmented moles and other nævi, especially since workers in human genetics (McKusick 1956) have demonstrated, in such diseases as the Marfan syndrome, a close genetic linkage between superficially trivial anatomical characters and grave hereditary diseases

OBSOLETE DEFENCE MECHANISMS

The suggestion that obsolete defence mechanisms from very remote dates in human evolution can be reactivated under the influence of emotional stress or long-continued anxiety (Harper 1953) seems less improbable in the light both of the clinical facts and of the collateral evidence deriving from the influence of pædomorphism in the recent development of the human brain This concept—that in certain highly progressive species, including man, evolutionary advance has been achieved by retention in the adult organism of structures formerly found only in the fœtal stages of the species—was first given the name of "pædomorphosis" by Garstang (1922) Hardy (1954) emphasises the close identity of Garstang's theory with Bolk's (1926) thesis of "fœtalisation" especially of the human skin de Beer (1951) wrote "It must not be pretended, of course, that pædomorphosis itself can account for the essential character of man—his mental capacities, we may, however, say these could not have been evolved without pædomorphosis" The clinician who appreciates the profound anatomical significance of a pædomorphic element in modern human evolution may properly inquire into the possible impact of such a phenomenon on the physiology and diseases of contemporary man Should it prove true that anatomical characters of fœtal type have been significantly retained in the human adult, a hypothesis that certain illnesses are based upon "morbid echoes" of archaic defence reflex patterns deserves careful examination

In relating human illness to reflex defence patterns, three groups of possible physiological mechanisms might be considered

Group 1—Those reflex patterns that are present and are still used for their physiological purpose in man Under certain adverse conditions of the environment, I suggest, a close association may exist between the reflex defence mechanism and a grave pathological process In this connection I shall refer with frank but necessary oversimplification, to the ætiology of phlebothrombosis

Group 2—Here no physiological service is immediately obvious at human level, but the clinical course of certain diseases suggests that they may be associated with obsolete reflex defence patterns of vital importance in the mammalian forebears of man Peptic ulcer can be an illustration here

Group 3—These reflex patterns are so archaic that it might seem absurd to suggest that human illness could be related to them Yet I believe that this will be shown to be true Proof of the existence on human skin of common structures relating man to the amphibian-reptilian era of his evolution will encourage the further investigation of what may prove to be an important new aspect of disease As illustrations, I shall mention, with diagrammatic oversimplification, three illnesses allergy, diabetes, and certain neoplastic states

Group 1

Every physician who has practised in the wards of hospitals where acute cases are nursed must have been puzzled by the frequency with which excellent work meets the unexpected and often grave complication of pulmonary embolism, due to detachment of a clot which has formed in the veins In relation to my hypothesis, the significance of this group of illnesses lies in the laboratory evidence that, in the lower mammalia and in man, blood tends to coagulate more quickly when danger threatens Stoker (1945, 1952) has demonstrated a considerable reduction in the clotting-time of rabbits after an incident causing them fear A similar reaction has been demonstrated by him in human beings under emotional stress Hunter et al (1941), in 351 unselected consecutive necropsies, examined the calf muscles macroscopically and microscopically and found antemortem clots (often bilateral) in rather over half of them

Deferring to most contemporary opinion, the clinician, losing his patient from massive pulmonary embolism consequent on phlebothrombosis, attributes the tragedy to rest in bed, to a fall in blood-pressure, or to debility. But observation over many years has convinced me that fear, or lack of confidence by the sensitive patient, has sometimes played a significant part Doctors, nurses, and administrators should be taught these physiological and clinical possibilities and recognise their implications Though nervous patients often find security in the wards of a hospital, and are relieved of some of the morbid potential of their anxiety in this environment, others react unfavourably to the often little-concealed events of the general ward It may well be that some of the cases of phlebothrombosis attributed to the uncomfortable seats in air-raid shelters were associated with this shortening of the clotting-time in the presence of fear

Here, then, is one example of an illness whose precipitating cause may be the morbid echo of a physiological process This particular process, we may suppose, was originally evolved, perfected, and selected because it prevented blood-loss in battle or in flight and so conserved the integrity of the blood-volume for escape or victory

Group 2

Harvey Cushing (1932) drew attention to the enormous literature, the vast number of theories, and the conflicting evidence surrounding the local lesion in peptic ulceration He expressed his opinion that, whatever the exact mechanism causing the local lesion might be, it was in the nervous system of man that the true causation of this illness would be discovered It is increasingly accepted that in the modern prefrontal areas of the human brain are centres closely linked with the age-old autonomic system. Brandt (1922) suggested that the parasympathetic antedates all other nervous structures in phylogeny, except the very early endocrine system Should pædomorphosis be proved to have conditioned man's recent evolution, apparent inconsistencies may be better understood, and the possibility that this type of illness may be based upon an obsolete physiology may be established as a fact In a feeding animal faced with an emergency in which a maximal supply of blood to the skeletal muscular system was required, we may discern a reflex mechanism that, by violent closure of the pylorus and the act of vomiting, halted digestion When fear and anxiety produce a morbid dynamic of tension in the human brain, some echo of this reflex may, I believe, be producing the organ dysfunction and damage

Group 3

Let us now briefly examine the distant end of the time scale, the amphibian-reptilian epoch of human evolution Elsewhere I have described manifestations of allergy as possibly based on the integrated oxygenating reflexes of skin, lungs, and gills—a normal physiological mechanism in the distant amphibian era (Harper 1948, 1951, 1953, 1955) I believe it is but the logical application of a true hypothesis to seek for other illnesses in this third group of reflex defence patterns, in view of the unique, yet very common, reptilian structures demonstrated on human skin by Laidlaw and Murray (1933) in their classical work on pigmented moles and their relationship to the evolution of the hair follicles in man

Long before the discovery of insulin, Osler (1892) wrote of diabetes mellitus "Mental shock, severe nervous strain, and worry precede many cases" Twenty-five years' experience in directing a diabetic clinic have convinced me that this mysterious and highly complex illness will be recognised, in some of its forms, as a disease of stress It is perhaps significant that the islet tissue of the pancreas retains its own autonomic nerve-supply, that to the beta cells being especially heavily innervated by the age-old parasympathetic system, so closely connected in the distant past with archaic reflex patterns of defence

Is it possible that the future may reveal knowledge that will justify another unexpected, yet I suggest logical, extension of the hypothesis, and bring within its scope as "morbid echoes" of this third group of reflexes certain types of malignant cell-growth? Remarkable regeneration of entire limbs after damage was a commonplace event in the amphibian-reptilian epoch of man's evolution The nature of the physiological forces at work in the organism while such extensive injury was being repaired is still unknown The process of such massive yet orderly repair can still be watched in the axolotl, that remarkable example of neoteny (extension of the larval stage), where mature reproduction occurs in the larval form of the amphibian *Amblystoma tigrinum* We cannot at present comprehend these physiological mechanisms even in such lowly organisms I believe, however, that in the reactions of man's body to certain exogenous and endogenous carcinogenic stimuli we may yet find that we are witnessing the results of a distorted and destructive physiology of archaic origin that formerly furthered active yet purposeful cell-growth after injury The influence of anxiety and mental shock on the course of a malignant illness has become increasingly apparent to clinicians (Ogilvie 1957)

CONCLUSION

The theory of evolution has become one of the great cosmic generalisations, and in whatsoever sphere it has been wisely applied it has enlightened what before had been an ill-defined field of human experience The time is ripe for its logical and bold application to clinical medicine

Congresses

GYNÆCOLOGY AND OBSTETRICS

At the second world congress of the International Federation of Gynæcology and Obstetrics, held in Montreal on June 22–28, 61 nations were represented

Canada's Problems

Mr **Waldo J Monteith**, Canadian Minister of National Health and Welfare, remarked that Canada is the third largest country in the world, occupying $3^{1}/_{2}$ million square miles, with a small population of 17 million largely based on a 200-mile strip across the country's southern border There is disparity of progress because Canada has been settled in waves, first Quebec, then Ontario, and the west some hundred years later, only now is the north being settled

Disordered Uterine Activity

Professor **Beloshapko** (U S S R) said that the idea of regulating the character of labour was generally accepted, and he drew attention to the vagaries of uterine action mentioning precipitate labour and inertia Inertia he believed to be the more important Having stated that the aim in uterine inertia was to reduce the necessity for operative procedures, he described many methods of stimulating uterine contractions In his summary of prophylaxis and treatment he stressed psychoprophylaxis, exercises, massage, and ultraviolet radiation, and the correction of sleeplessness by having special sleeping-rooms and by the careful organisation of the leisure especially of long-stay patients He believes in adequate feeding and in not putting the woman to bed too soon in her labour

The Hypothalamus

Prof G W **Harris** (Britain) described very clearly the careful experiments by which the relationships between hypothalamus, pituitary, reproductive organs, and breasts were established Impulses from the hypothalamus reach the anterior lobe of the pituitary gland by way of the vascular portal system, as has been shown by transplanting the pituitary gland first into the capsule of the kidney, when its hormone activity ceased, and then returning it to its original site, where the portal circulation was reestablished and pituitary function restored Not only has the hypothalamus a depressant action on the adenohypophysis but also there is a stimulating action Follicle-stimulating hormone may be released under the stimulation of tumour, and Professor Harris suggested that precocious puberty resulting from hypothalamic lesions may be explained in this way

The humoral interplay between hypothalamus and adenohypophysis is clearly established by the absence of any effect if the pituitary is stimulated electrically, in contrast to the marked effect if the hypothalamus is given a similar stimulation

The relationship between hypothalamus and neurohypophysis is by contrast a nervous one Stimulation of the hypothalamus leads to the production by the neurohypophysis of oxytocin, which in turn causes pregnant uterine muscles to contract and also causes the ejaculation of milk from the breast by its action on the contractile tissue in the mammary gland

The precise routes by which afferent stimuli reach the hypothalamus are not clear, probably because they are so varied This whole study accords with the known effect of emotional and other environmental stimuli on both uterine action in labour and successful lactation It may now be said that the precise way in which fear and other harmful stimuli affect parturition and lactation is well on the way to being worked out

Amniotic Membrane

Professor **BAUTZMANN** (Germany) gave a fascinating account of the muscular activity of the amniotic wall in the chick embryo and compared this with the absence of any corresponding muscular activity in higher mammals He expressed the opinion that the rhythmic activity of the amniotic membrane, which was illustrated by film, had the important effect of moving the nutrient material around the chick, and he showed conclusively that this movement was independent of fœtal activity

Fertilised Ovum

Dr **BRADLEY PATTEN** (U S A) said that the fertilised ovum develops a thick wall around it, and this has two purposes (1) it acts as a barrier to the entry of other spermatozoa, and (2) it prevents the enlargement of the fertilised egg during the early days of division and subdivision and so keeps it small enough to pass through the fallopian tube Apparently, too, this cluster of cells with its thick envelope is particularly sticky opposite the inner cell mass and this facilitates implantation Dr Patten described and illustrated the development of the fœtal circulation He showed how the primitive tubular heart begins to contract before any connection has been made with the primitive blood-vessels, and illustrated the early formation of blood-cells and the coalescing of primitive blood-vessels

Sex Chromatin

Prof **MURRAY L BARR** (Canada) spoke briefly about the three methods of examination for female sex chromatin—by mucosal smear, skin biopsy, and blood film He drew attention to the occasional flattening out of the chromocentre as a source of error The two main groups of disordered sexual development comprise those exhibiting partial masculinisation and those exhibiting intersex

It is important to distinguish the adrenogenital syndrome from male pseudohermaphroditism so that cortisone may be started without delay and the severe metabolic crises characteristic of the untreated adrenogenital syndrome prevented He also drew attention to the possible virilising effect on female infants when the mother is treated with progesterone during her pregnancy

Turning next to gonadal dysgenesis, he pointed to its relationship with coarctation of the aorta The ætiology is not known

In male pseudohermaphroditism there is deficient interstitial-cell development with a consequent trend towards femininity in development

The testicular feminising syndrome usually associated with the name of Kleinefelter presents the unusual combination of testes, absent uterus, female external genitalia, and normal female stature There is failure of masculinisation of the external genitalia and clumping of the Leydig cells Half of these cases are sex-chromatin-positive and half negative

Exceptionally some spermatogenesis has been noted even in sex-chromatin-positive cases Professor Barr drew attention to the greater frequency of this syndrome in mental defectives and put forward a plea for a closer study of these cases, believing that such a study might lead to some understanding of the causes of mental deficiency—a subject which he maintained had been much neglected by medical research-workers

Uterine Contraction

Dr **ROBERTO CALDEYRO-BARCIA** (Uruguay) reviewed the investigations carried out by the team in Montevideo on uterine contractility by the simultaneous recording of the pressures in different parts of the uterus under different conditions He also presented new work based on the continuous recording of amniotic-fluid pressures in labour He defined uterine intensity of contractions as the difference between the resting and contracting uterine pressures, the frequency of contractions as the number per ten minutes, and the uterine activity as the product of the intensity and frequency, uterine activity is expressed in Montevideo units

As pregnancy advances there is steadily increasing uterine activity until at the onset of labour this amounts to about 100 Montevideo units by the second stage the activity has increased to 250 Montevideo units Distension of the cervix leads to nervous impulses reaching the hypothalamus and then the posterior pituitary with consequent release of oxytocin and augmented uterine action

The simultaneous recording of myometrial activity by microballoons placed in various parts of the uterus has shown up the difference between the normal and abnormal patterns Though the acme of the contractions is reached normally by all parts of the myometrium at the same time, the onset of the contraction starts at the cornu and spreads from here throughout the uterus The pain of labour is caused by cervical distension and later perineal distension Much work on abnormal action was described Hypoactivity of the uterus only led to 40 Montevideo units, and this is not enough to cause labour to progress In such cases a continuous oxytocin drip is used, and the fluid is given with great accuracy by means of an infusion pump

Adrenaline first inhibits uterine activity, and then there is a rebound phenomenon with increased activity Pethidine and morphine have no effect on uterine action Toxæmia is usually associated with good uterine activity Spinal anæsthesia has no effect on normal uterine activity, but if the resting tone of the uterus is high, perhaps because of fear, then it can be beneficial The dorsal position leads to better muscular activity than the lateral positions

Placental abruption raises the tone and no drug has so far been found to lower this, artificial membrane rupture is the best treatment, but it does not lower the tone

If hydramnios with high resting tone is treated by membrane rupture, the tone is lowered and labour is likely to ensue in contrast hydramnios with an initial low tone may be tapped without such a likelihood of labour starting

Dr Caldeyro-Barcia then went on to describe the qualitative faults in uterine action, showing tracings of irregular contractions Several centres of contraction, acting independently, can each have the effect of inhibiting and largely neutralising each other's actions In some cases, at least, intravenous oxytocin in carefully controlled quantity has been found to have a striking coordinating effect Spinal anæsthesia had a similar effect, as did hypnosis

Probably fear and other harmful stimuli adversely influence uterine action by way of the adrenals and by the release of adrenaline and noradrenaline

---

Parliament

Ten Hospital Years

As " chairman of Parliament's own hospital ", Lord **Nathan** appropriately opened the debate in the House of Lords on July 2 on our hospitals and their progress during the past ten years The time was, he thought, suitable for such a review, for the start of the National Health Service had in many ways marked a revolution in the social life and habits of the country It had affected vast numbers of the population, and it had influenced the standing and procedures of the medical, dental, and nursing professions It was, perhaps, the central feature of the Welfare State The hospitals were an important part of the service, and he thought that the Ministry of Health and the doctors, nurses, and administrators should be congratulated on the adaptability, assiduity and devotion they had shown in running the hospitals in the unfamiliar circumstances of the last ten years He admitted that he was surprised, though delighted, by the amount of voluntary service still offered At the Westminster Hospital the number of volunteers was greater than ever, which showed that people would not consent to being deprived of the opportunity for service

BRICKS AND MEN

Turning to finance, Lord Nathan said that it had been a period when " I would " had had to wait upon " I can ", and he was uneasy lest capital expenditure be unduly restricted In the past years when money was scarce there had been a tendency to plan hospitals as small as might be, but, though the need for beds had not grown, Lord Nathan suggested that, with the coming of new techniques, the need for more space had grown greatly He urged the Ministry when building new hospitals not to limit their building to the space actually needed at the moment but to exercise imagination and provide for the fresh disciplines and methods of tomorrow We could not retain in this country the young men on whom the future of medicine depends unless we offered them the opportunity of developing their powers and their careers Lord Nathan doubted whether the Ministry was justified in asking hospitals to contribute, for buildings, money from their endowment funds private funds were being used to subsidise expenditure for which Parliament had made the Ministry responsible

Lord **Amulree**, speaking as a member of the medical staff of a London teaching hospital, agreed that during the past ten years the hospital service had improved Many hospitals which had been rather poor were now very good, and there had been no corresponding falling-off in the work of the good hospitals But he was a little frightened about the future If too rigid a ceiling was placed on the amount of money available, then we were bound to get some kind of falling-off Medicine was expensive work to carry out properly, and though one could economise one could not avoid spending money At present there were many drawbacks in hospitals—for instance, operations had greatly increased in number and complexity, and many surgeons were now working under conditions of discomfort if not of difficulty But, provided the staff and equipment were good, he did not think it necessary to have brand new buildings to do good work, nor did he think that there was great need for more beds than at present On the other hand, there was need for more accommodation for infirm elderly people who required care, though not in hospital

Lord **Evans**, in a maiden speech, said that his interest and occupation was with bedside medicine rather than administrative medical affairs He was sure that the quality and standard of medicine must depend on the quality of the teaching hospital, and he pointed out that the teaching hospitals train most of the teachers of the ancillary services as well as undertaking their primary duties of the care of patients, the teaching of medical students, and research Since the start of the N H S little had been done for teaching hospitals save the provision of funds to keep the machinery going They had outmoded inadequate accommodation for patients, teaching, and research Of the twelve London teaching hospitals only two had ever been rebuilt, yet many had been badly blitzed during the war Surely, he said, there must be some limit to the enjoyment of such austerities Surely it was absurd for the teaching hospitals virtually to mark time till every other hospital caught up The immediate past president of the Royal College of Surgeons of England [1] had suggested that hospitals should be encouraged to seek additional sources of finance outside the Government budgets of the N H S For the teaching hospitals, to the minds of many, this would be a welcome return to old practices and in keeping with their heritage In appealing to the community, to industry, and to philanthropic individuals they would follow the example of the universities, and such efforts might enable us in a few years to see several new teaching hospitals in this country

Lord **Moran** said that it was dangerous to measure the progress of a science by the foot-rule of the administrator, but he thought it just to congratulate the Ministry on a remarkable administrative achievement They had decentralised the consultants in this country Because consultants were paid for their hospital work it was no longer necessary for them to live in the great centres, and in almost every part of the country there were now specialists in every branch of medicine Their number had also been greatly increased Moreover the patient could not only see a consultant in hospital, if he was too ill to go there he could call a consultant to his house, and in 1956 there were 265,000 domiciliary consultations Decentralisation had also made possible the upgrading of hospitals throughout the country These two reforms would by themselves have justified the existence of the N H S, but the conditions in mental hospitals had also been transformed Doors had been unlocked, the padded room was a thing of the past, 80% of the patients were voluntary boarders, and outpatient departments had been opened People from America, the Commonwealth, and all over the world came to see how these institutions should be run, and it had been done without rebuilding

REMUNERATION AND OPPORTUNITY

Another reform, Lord Moran continued, which the N H S had brought was concerned with the remuneration of consultants Before the service the consultant obtained his remuneration from private practice Now most consultants got their remuneration for hospital work A man about 40 would get £3255 per annum as a maximum basic salary, and for the rest of his working life he would get no more unless he was given a merit award His material prosperity now depended on his professional efficiency, whereas formerly it was dependent to a great extent on his personality There had, Lord Moran said, been many arguments for and against these awards, but of the bodies that had given evidence before the Royal Commission all save one had spoken in their favour Turning to the future,

---

[1] See *Lancet*, 1958, i, 1270, *Brit med J* July 5, 1958, suppl p 5

Lord Moran said that it was important not only that we should get the right quality of men into medicine, we should reward adequately those who submitted to the discipline and years of training to become a consultant If the proper balance between the pay of the consultant and that of the general practitioner was not maintained, recruitment would wither In the last resort the efficiency of the service would depend not on administration but on the quality of the entry and the training of the students He admitted that he was uneasy about the quality of the entry Not long ago middle-class parents paid for the fees of all medical students Now two-thirds were maintained by the State and were selected by examination without any test or regard to character He believed that one could not select people solely on examination for a profession like medicine which required the human touch more than almost any other

He admitted that there was considerable discontent at present among general practitioners but he did not believe it was based on remuneration The cause was to be found in the general decline of the status of general practice It had begun when people who were seriously ill began to feel that they were well advised to go into hospital It was mortifying to the doctors to find that the patient in a crisis preferred to put himself in the hands of a complete stranger The N H S had exacerbated this because, with consultants on their very doorstep, the general practitioners were unable any longer to make those modest excursions into the consultant field which had lent flavour to their life In his view the remedy was for the pick of the general practitioners to follow their patients into hospital and to become part of the staff of the hospital He believed that this should be the most important administrative move in the next decade If that was not done, with a discontented profession, efficiency must wither, whatever the remuneration

The Earl of CRANBROOK shared Lord Moran's hope that the general practitioner should be brought more and more into the hospital But his own feeling was that the hospital needed to be brought more and more outside itself and into contact with the general practitioner and those who were serving the public in their homes

ADMINISTRATORS, BOARDS, AND COMMITTEES

The Earl of LUCAN raised the question of hospital administrative staff The Hall report had shown that the service was not offering a sufficiently attractive career to get the best type of administrator Yet those who were responsible each year for several hundred million pounds of public money should be of the highest quality On the training side there was a serious gap A national scheme had been started a year or two ago, but the number of students was 24 and the course lasted three years It could make only an infinitesimal contribution to the staffing problems of the 400 hospital boards As a result, all the training these young men usually received was by being attached to different departments and different hospitals It seemed to him that much more systematic and positive training was needed Turning to the vexed question of capital investment and hospital building, Lord Lucan said that when he saw the millions of pounds being spent on office buildings, which were often put up for prestige purposes, he wondered if historians in a hundred years would not be puzzled how we could have got our priorities so wrong

Viscount ASTOR asked for an inquiry into the administrative system of our hospitals He felt that most hospital committees were far too big and that the work could be done by half the number of people in half the time Members went into far too great detail on many minor matters which in ordinary administration should be done by a staff, and at the same time the ordinary house-committee had practically no responsibility for the hospital which it was supposed to know intimately The hospital management committees were too big and proliferated so many subcommittees that it was difficult for any busy man to be a conscientious member He believed that we needed small committees, meeting perhaps half as often, with chairmen and officials having greater responsibility for many minor decisions We should try to recruit our hospital officials from a rather wider circle and be prepared to bring in some of those of great administrative ability who were being "axed" from the Services but yet had leadership and knowledge of organisation of people

Another point was the almost complete separation of the medical and lay side Some doctors sat on the management committee but no layman knew anything of what went on at the doctors' committees So there were two parallel chains of committees both looking after the same hospital, "If one suggests that even the chairman of the hospital committee should go to the doctors' committee—well, my word!" He believed that there should be far greater confidence and mutual knowledge than at present

THREE ACHIEVEMENTS

Lord STRATHCLYDE, replying for the Government, suggested that the magnitude of the undertaking was worth a little thought There were in the hospital service in Great Britain some 3700 hospitals and clinics employing 374,000 full-time and 94,000 part-time staff, handling 4½ million inpatients and some 56 million outpatient attendances, and spending something like £400 million in a year It was hardly to be expected that an undertaking of this size, financed from public funds, should not have thrown up many problems during the years in which it has been taking shape, but it would be grossly unfair to all the people running the service to give the impression that the Government were so preoccupied with the problems that required solution and the possibilities of the future that they had no time to spare for appreciation of what had already been done Looking at the whole picture from the point of view of the central Government three features were notable

First, the coming of the hospital service had resulted in specialised medical skill being much more widely available throughout the country The number of specialists employed in the hospital services in Great Britain at the end of 1957 was not far short of 8000, an increase of nearly 33% on the figure even at the end of 1949 when the hospital service had already begun to make its impact Mental health especially had gained by this It was true that we still had not all the specialists we should like in this field, but an entirely new approach to the problems of mental illness has manifested itself in recent years

The second feature was the sheer volume of the work that had been handled, compared with the very limited physical expansion that had been found possible In these last eight years the number of inpatients had risen by 29% in England and Wales, and 43% in Scotland There had been a 6% increase in the number of beds but this had been largely achieved, not by new building, but by bringing into use beds which were formerly idle He did not want to give the impression that the Government did not consider that new building was necessary, but he thought it fair to give credit to the doctors, nurses, administrators and who, despite shortages and obsolescence, had yet achieved so much

The third achievement was the progress made in the integration of the service In 1948 nearly 3500 hospitals were taken over—many completely independent and separate, and others grouped only within a local-authority area He had no doubt that there were still instances where it was far from perfect, but the service today was a reasonably coherent entity and not just a collection of individual hospitals

Amendment of Registration Procedure

On July 2 Lord COHEN OF BIRKENHEAD introduced in the Lords the second reading of the Medical Act 1956 (Amendment) Bill which removes certain anomalies of the present system of medical registration.[1] He informed the House that the Bill had passed all its stages in the Commons without dissent, and that all interested parties had concurred in its provisions

Royal Assent

The Opticians Bill and the Disabled Persons (Employment) Bill have received the Royal Assent

---

QUESTION TIME

Hospitals Staffing Working Party

Mr Kenneth Robinson asked the Minister of Health whether it would be open to this Working Party to make recommendations on the levels of consultant staffing either in the country as a whole or in particular regions, and approximately how long he expected the Working Party would require to complete their task —Mr Derek Walker-Smith replied As the Working Party's task is to study the principles on which the medical staffing structure in the hospital service should be organised, they will not be concerned with the numbers of consultants as such No estimate can be made yet of the time they will require, but I am sure they will proceed as quickly as they can Mr Robinson Does the Minister not appreciate that the level of consultant staffing is a basic consideration, not only to the senior registrar problem but to everything else that the Working Party is supposed to be examining? Does he not realise that unless they can recommend on this matter these distinguished gentlemen will be wasting their time?—Mr Walker-Smith It is for these distinguished gentlemen themselves to decide what matters they will need to go into so that they can discharge the terms of reference, of which they are aware and which they have accepted

Mr Robinson asked the Minister why he did not include either a psychiatrist or a layman with special knowledge of the staffing structure requirements of the mental hospitals among his nominees on the Working Party —Mr Walker-Smith The reason is that the Working Party as constituted is well equipped to cover the hospital service generally and is free to obtain evidence about particular classes of hospital, mental and others Mr Robinson Is the Minister not aware of the indignation which is felt among psychiatrists at the way they have been excluded from this important body? Does he not realise that the needs of the mental hospitals, even concerning the staffing structure, may be very different from those of general hospitals? Will he not reconsider the matter?—Mr Walker-Smith I am not aware of any such indignation To give representation to all the various specialties and to the different kinds of hospitals which would logically follow, would only increase the size of the Working Party far above the number of 12 and would certainly have delayed the results of its proceedings Dr Edith Summerskill This is a curious omission, because the hospitals which are grossly overcrowded in every area are the mental hospitals The main problem very often is lack of staff or the proper allocation of staff Therefore, to omit a psychiatrist from a committee which is considering the overall allocation of staff is a little peculiar —Mr Walker-Smith The Working Party consists of people all of whom have great experience in the hospital service They can, I am sure, be trusted to obtain such information as they will need in regard to all the particular classes of hospitals and specialties with which they are concerned Mr Robinson In view of the unsatisfactory nature of this and the previous reply, I give notice that I will raise the matter on the adjournment

Inspection of Imported Egg Products

Mr Arthur Blenkinsop asked the Minister what action he was taking to ensure that imports of egg white were fully inspected before release to manufacturers —Mr Richard Thompson, parliamentary secretary to the Ministry, replied Port health and other local authorities have been asked to pay special attention to the sampling of imported egg products for bacteriological examination At present the authorities try, whenever possible, to sample every batch It would not, of course, be practicable to sample every tin Mr Blenkinsop Does the Minister not agree that the reports from his own Ministry show there is a large proportion of samples taken which show a high level of infection?—Mr Thompson Yes, we recognise that there is a problem here, but we consider that the present arrangements for sampling are the best we have tried and also that the wish which we have made known to the exporting countries ought to provide a solution

In England Now

A Running Commentary by Peripatetic Correspondents

In our early youth we were sick on the second storey of the Eiffel Tower, and since this incident we have had little taste for heights It is difficult to persuade us to enter an aircraft or even to paint the dining-room ceiling, and on our seaside holidays we are a skeleton at the feast While our dependants skip gaily along the smugglers' path, dislodging loose stones into the gulf 300 feet below, we are to be found progressing carefully on hands and knees, gripping the landward vegetation in an ecstasy of spasticity

We were therefore disturbed to find during our last summer holiday that family opinion had committed us to visiting a lighthouse Our confidence in the outcome was not enhanced after we had battered our way in a 50-knot wind to the foot of the structure, by the discovery that we were expected to sign away our chances of survival in advance "I the undersigned", said the form sombrely, "hereby acknowledge agree and undertake for myself and for and on behalf of all minors noted hereunder as under my sole charge that no action suit claim or demand shall lie or be made or instituted in respect of any accident death injury loss or damage sustained or occurring by or to us or to any of us during the said visit I will indemnify", went on the form, clinching the matter, "keep indemnified and save harmless all departmental servants officers and agents against all actions suits claims and demands "

The lighthouse-keeper was sleeping, and his assistant was seeing a man about a wreck, but trustingly permitted us to make the ascent unaccompanied The minors under our sole charge occupied themselves happily in counting the 329 steps, and no accident death injury loss or damage was sustained or occurred on the way up In the lantern room, however, the rarefied air and the presence of several other minors had the worst possible effect Within seconds the lens holder, bearing the legend ON NO ACCOUNT TOUCH THE LENS HOLDER, had been seized and was rotating madly on its axis to the accompaniment of wild cries of exaltation A dissipated-looking minor of a reflective turn of mind had begun to try to drop marbles on the head of the assistant keeper, and a small ginger group was running at high speed round the outside gallery, restrained from falling into the immeasurable depths only by a single rail at chest height After one vertiginous glance through the open door we were forced to concentrate on the lighthouse keeper's box of dyspepsia tablets under the map of the local rocks and reefs While we were thus engaged, the door to the outside gallery slammed and locked itself, the minors under our sole charge, happening to be on the wrong side at the crucial moment, set up a prolonged bawling With set and pallid face we descended the steps to fetch the assistant keeper with a key

When order had been restored and we had indemnified and saved harmless the assistant keeper, we reached the ground again in an atmosphere of mutual congratulation Only too soon a rough count established the fact that our personal quota of minors had been reduced by one Elected a search party by popular acclaim, we climbed the 329 steps for the third time, to find our youngest minor flat on her stomach in the lantern room, deeply immersed in the lighthouse keeper's *True Love Stories* and sampling his dyspepsia tablets

For our next holiday we are going to the Cotswolds

* * *

I suppose this week most of us have been looking back over the past decade and asking ourselves how we have fared According to the popular press we G P s have had a raw deal We are the underdogs of the health service and our yelps for fair play against those bloated plutocrats the consultants should wring the heart of every honest man We work twenty-four hours a day We even have to pay to get a holiday We are bullied by our patients and are treated with contempt by the hospitals

Why then, despite all these horrors, are there dozens of applications for every vacancy in this underdog service?

Is it possible that the Press is not quite accurate in its accounts of our miseries? Perhaps some of us do see eye to eye with our friends the consultants. Perhaps, though of course we wouldn't mention it, most of us love our work. Perhaps we enjoy treating our fellow men in their own homes, even though it means long hours and short holidays. Perhaps, though we hardly dare whisper it, some of us feel that general practice has gone forward during the last ten years and we are proud of it.

* * *

Everyone knows how enlightened and progressive mental hospitals are these days, but I was still unprepared for the reaction of a colleague who was trying to interview patients, in what would once have been called a "back ward", despite frequent interruptions from a character who in a less permissive era would almost certainly have been stowed safely away in a padded cell. Losing patience at last, he flung down his pen and exclaimed indignantly, "Really, Sister, this place is getting to be like a madhouse."

* * *

It is obvious to those who read the literature that getting satellites into space is a matter of stages. We didn't actually get anything into orbit. Initial trials were carried out with 6d and 3d rockets. The smaller rocket was fixed to the larger so as to allow only an upward separation. Firing of the second stage was by a predetermined length of catherine wheel, which was inserted into the vitals of the smaller rocket. When the bugs had been ironed out of this phase the final trial was carried out with a 2s 6d, a 1s, and a 3d rocket. This is only one stage short of space according to junior's calculations. We were reduced to one test vehicle because of lack of enthusiasm in the female part of the family, who did not like catherine wheels being cut up and refused to allow more than one 2s 6d rocket.

This was fired on Guy Fawkes night last year. The count-down went according to plan. The first stage was fired as the fuses of the other two were lit. Unfortunately the smallest rocket fell off, its connections being apparently strong enough only for 6d boost, but the other two stages were away. The end of the first boost was marked as planned by a display of green stars. There was a delay of the cut-in of the next motor, probably because we had to use a different make of catherine wheel to our usual. The second stage could be just seen as a faint gold spot curving over and gradually increasing speed as it fell. Nearing the ground it burst into life and gathering momentum at an alarming rate hit a distant neighbour's roof and disappeared. There was a far-off crash of falling tiles, then silence. The third stage burst into life and vanished into the potting shed. We crept indoors. We are now talking to our neighbour again. It had gold stars, apparently.

* * *

BEFORE AND AFTERTHOUGHTS

I thought I saw an A-line
A-twisted all awry.
I looked again and saw it not
—I cannot tell you why.

I thought I saw a Newton
In thought upon the shore,
I looked again and saw it was
A man I could ignore.

It seemed I saw a System
Of thoughts all bright and new,
I looked again and saw they were
A muddled, motley crew.

I thought I saw Time's chariot,
Wing'd horses all before,
But after, when I looked again
They were in front no more.

Had we but world enough and space
These theories, Doctor, were in place,
Do write again, but ere you start
Put Reason's horse in front of Fancy's cart.

Letters to the Editor

ORTHOPÆDICS, INDIVIDUALITY, AND THE HOSPITAL SERVICE

SIR,—At a time when we are reviewing the work of the past ten years I should like to stress the tradition of individual effort and the difficulty of giving it expression in the hospital service today. The difficulties are largely inescapable when control is in the hands of coordinating committees and administrators largely out of personal touch with the day-to-day work of hospitals and for whom organisation, centralisation, integration, and rationalisation are prominent thoughts. Tradition should not slavishly be followed: many traditions hold bad features. The Ministry of Health has, however, been right in emphasising the need to preserve the good traditions of the voluntary hospitals (though it is often very difficult for the house committees of these hospitals themselves to maintain them). The idea often is given no more than lip service.

I am worried by the discouragement of a sense of responsibility and initiative at the periphery and particularly worried by a tendency to destroy certain valuable schemes of hospital service which, in advance of their day, were built up by the enlightened and creative efforts of pioneers like Robert Jones and Henry Gauvain. Naturally I take the orthopædic service, for it is the one I know best and because (as I pointed out in *The Lancet* in 1944[1]) it possessed features which we can now see foreshadowed many of the developments of the national hospital service itself.

It is unfortunate that orthopædics is often thought of as a purely surgical special branch of medicine. If it were so there would be some excuse for regarding the orthopædic idea of segregation, teamwork, continuity of treatment, and rehabilitation as an anachronism in special hospital units. On the contrary, orthopædics is a very general rather than highly specialised branch containing a dominant interest in medicine itself. Sir Henry Gauvain, who started his work at Alton fifty years ago, exemplified one aspect of this physician's outlook and he built up a splendid institution. At Oswestry, Oxford, Stanmore, and Pyrford similar organisations were established by the pioneers. They involved a compact organisation of a central hospital fed from and feeding into dispersed outpatient clinics with a team of surgeons and their specially trained groups of aftercare sisters, orthopædic nurses, secretarial staff, workshops, &c. In each the emphasis varied and the model was that at Oswestry. These schemes and others like them (and indeed others which still should be established) have a special approach to the whole man (starting with childhood), his social background, and the continuity of his treatment leading to rehabilitation.

The compactness of the organisation with its individual leadership and fine teamwork is now faced with a changing clinical responsibility. Although tuberculosis, rickets, osteomyelitis, and we expect, poliomyelitis are diminishing, nevertheless the congenital and developmental anomalies of childhood, trauma, arthritis, and the locomotor lesions of stress will continue to provide a large number of long-term problems for which treatment in these schemes is well found. It would not be right to say that there is great overt evidence of destruction, yet in this-and-that small way orthopædic institutions are being eroded. There is loss of individual identity, and the consequent weakening of morale, lack of proper support for the training and wellbeing of the orthopædic nurse and aftercare sister, and the separation of sections of the work of an organisation into the hands of new consultants working largely in isolation from the parent team, which results in dispersal of clinical material.

---

[1] Capener, N. *Lancet*, 1944, ii, 355.

This dispersal may be considered to be countered by the association of the orthopædic surgeon with his general medical and surgical colleagues in local units and by the association of the patient's treatment nearer his home. Of course orthopædic surgeons should be part of the team in every general hospital, but this need not be incompatible with his belonging to another team as well A patient's separation from the neighbourhood of his home has disadvantages but is less of a problem now than it was thirty years ago, and in any case is outweighed by the advantages of the greater experience and skill to be achieved in the special hospitals, particularly when these have an efficiently coordinated aftercare clinic system.

I am not so senile as to think that these orthopædic-hospital schemes could not be improved What I do say is that it is very difficult to do the necessary individual creative work in the atmosphere of central group administration.

There is one final point The orthopædic services of this country are the envy of foreign visitors, who so often have nothing of the sort. We owe it to the new Commonwealth nations to maintain and develop this type of organisation Abroad they still see tuberculosis and other crippling diseases in the dreadful form that we did thirty and more years ago, and their young men come to us to learn

Exeter NORMAN CAPENER

N H S STAFF COLLEGE

SIR,—The suggestion from Dr Parker (July 5) of a National Health Service Staff College is to be warmly welcomed We should, however, hesitate before advocating a Staff College exclusively for members of the profession We need to see an end to the rivalries for administrative authority At the last annual conference of the Institute of Hospital Administrators, it was sad to hear how much time was given to discussion of who was responsible to whom This, no doubt, is a natural preoccupation among lay administrators still looking over their shoulders to the days when medical superintendents were all-powerful figures in every aspect of hospital responsibility, but it is an attitude which stultifies initiative and innovation

The most advanced sectors of industry today have long recognised the vital contribution which technical training and background can make to administration The second industrial revolution we are witnessing today is being directed by a partnership of " lay " and technically trained management, applying the new knowledge of technology, operational research, and social science with an effective enthusiasm from which the Health Service has much to learn

After ten years of reaction against medical administration in the service, a new balance needs to be reached and a working partnership created between medical, nursing, and lay personnel An exclusively medical staff college may accentuate rather than resolve the existing divisions

The Administrative Staff College of the King Edward Hospital Fund is carrying out an imaginative and stimulating task, almost entirely among the lay staff of management committees The fund also runs a college for administrative nursing staff Could not the present Staff College be expanded to cater jointly for medical and other administrators ? I believe that a Joint Staff College, in addition to its function of training in the techniques of modern management applicable to a health service, would do much to define each partner's proper sphere of activity, and to infuse that sense of common purpose which the service so badly needs

Paddington General Hospital,

Medical Director

DEATH OF A BOXER

SIR,—I have followed the correspondence upon the medical complications of boxing with mixed feelings Dr Lyburn's last letter (July 5) goads me into reply, however

Surely among his boxing friends and acquaintances he has encountered traumatic progressive encephalopathy There now exists really quite a formidable literature upon the subjects of punch-drunkenness, on death in or shortly after a boxing bout, as well as on the occurrence of subdural hæmatomata and of traumatic carotid occlusion as a result of boxing The ophthalmic literature alone contains an impressive record of injuries to the eye

London, W 1 MACDONALD CRITCHLEY

REVERSAL OF SUXAMETHONIUM PARALYSIS WITH NEOSTIGMINE

SIR,—Dr Shegog Ruddell reports an instance of neostigmine-reversible suxamethonium paralysis in a child, and demonstrates once more that anticholinesterase decurarising drugs may be used with confidence in these circumstances[1]

In 1954 I drew attention to the fact that young children were inherently resistant to suxamethonium,[2] and in 1955 confirmed this, showing that the characteristic was unrelated to cholinesterase activity, and probably associated with no physical factor other than an inherent " state "[3] I am sure that had the biochemical estimations, including the serum-cholinesterase, been forthcoming in Dr Ruddell's patient, they would have been essentially normal More recently, with others, I suggested that changes in sensitivity to depolarising relaxants were more likely to occur in those patients showing an inherent resistance to the drug in the first instance[4] The clinical sequel of these two observations (that the young are prone to develop a " dual " response after depolarising agents) has been noted by Rees[5]

Better terminology would clarify the situation in the minds of many of us The terms " depolarising " relaxants, and " dual " response are misleading The expression biphasic response, illustrating consecutive rather than concurrent actions, would seem preferable[6] The second phase of this response represents the typical, and to be expected, non-depolarising effects of the so-called " depolarising " agent, and may be recognised and treated as such with confidence

In the presence of a raised endplate resistance to depolarisation the typical action of suxamethonium, already previously described,[7, 8] is slower in onset, less intense in effect, but mildly prolonged In this phase, if attempts are made to obtain (with the less effective agent) the immediate and profound relaxation usually associated with the depolarising action of suxamethonium, accumulative effects and further delay in recovery may follow This depression is reversed by anticholinesterase drugs

These circumstances do not contraindicate the use of suxamethonium, providing it is recognised that a slightly longer-acting and less effective " non-depolarising " agent is being administered, and precautions are taken to avoid overdose Antidotes should be used whenever indicated

---

[1] *Lancet*, 1958, i 1390
[2] Hodges, R J H, Harkness, J *Brit med J* 1954, ii, 18
[3] Hodges R J H *Proceedings of the World Congress of Anæsthesia* *Curr Res Anæsth* 1956, p 247
[4] Foldes F F, Wnuck A L, Hodges, R J H, Thesleff, S, de Beer, E. J *ibid* 1957, 36 23
[5] Rees, G J *Brit med Bull* 1958 14, 38
[6] Hodges R J H, Foldes F F *Brit med J* 1957, i, 373
[7] Hodges R J H *ibid* 1956 ii 1240
[8] Hodges, R J H *ibid* 1958, i, 1416

A non-depolarising block following the administration of suxamethonium may be anticipated not only in children and neonates It may be expected to arise whenever endplate resistance to depolarisation is present, inherently as in certain species, pathologically acquired as in myasthenia gravis and sometimes electrolytic imbalance, or induced (particularly in those with an inherent tendency) by drugs. This last may follow the administration of relaxants,[4] but may also follow the administration of drugs with no obvious clinical neuromuscular-blocking effects (e.g , oxytocin) [5]

Portsmouth **R J HAMER HODGES**

ANÆSTHESIA FOR THE EMPHYSEMATOUS

SIR,—In an annotation [1] you summarise the hazards of general anæsthesia and artificial ventilation in emphysematous patients The article goes on to say that despite its drawbacks artificial ventilation " is generally advisable for emphysematous patients undergoing extrathoracic operations as well [as thoracic operations,] since it is the only means of ensuring adequate gas exchange "

It is unfortunate that your article dealt exclusively with general anæsthesia, and that regional anæsthesia, either alone or in combination with light general anæsthesia, should not have been mentioned, for the latter provides good operating conditions, as well as adequate respiratory exchange in most cases Admittedly, in thoracic and upper-abdominal operations under regional anæsthesia, suppression of intercostal activity demands the use of controlled respiration just as in non-emphysematous patients, but in operations elsewhere adequate spontaneous respiration can usually be retained, if in doubt ventilation can be measured directly by switching a simple spirometer into the anæsthetic circuit from time to time

The retention of adequate spontaneous respiration has definite advantages, for while it exists the normal inflationary pattern of the chest is maintained, and alveolar ventilation-perfusion ratios remain relatively unaltered. But, as Campbell et al [2] point out, the imposition of artificial respiration is accompanied by an increase of physiological dead-space, and the hazards outlined in your article are added to this Besides the difficulties you mentioned there is some evidence that under light general anæsthesia and neuromuscular blockade surgical stimulation reduces the compliance of the lungs, so that the work of breathing is increased, and higher intrathoracic pressures have to be used to shift a given volume of gas [3]

The neuromuscular-blocking agents have made general anæsthesia so simple and safe that the pendulum has swung away from the more exacting methods of regional anæsthesia, which are falling into disuse Consequently, the present generation of anæsthetists-in-training find it difficult to obtain a good practical grounding in regional techniques, although these still have much to offer, especially in the emphysematous patient. Unfortunately skill in regional methods requires practice, and this is not always easy to obtain when slickness of " throughput " is so often the primary aim in many operating-theatres But consultant anæsthetists should see to it that their juniors do get the opportunities to achieve facility with regional techniques, otherwise the disciplines of the specialty will become depressingly narrowed.

Royal Victoria Hospital,
Montreal **P R BROMAGE**

SIR,—The remarks in your annotation of June 14 are very timely Extensive experience has shown that artificial respiration is imperative for all such patients undergoing major operations under general anæsthesia—regardless of the site of operation

A few points may be re-emphasised the administration of bronchodilator drugs should be an integral part in the maintenance of anæsthesia, and the rate of respiration and tidal volume should be monitored, together with the airway pressures These parameters may be accurately determined before induction of anæsthesia on the basis of the size and age of the patient, together with an estimate of degree of emphysema (simply determined by the breath-holding test and expiration time) [1] These must be adjusted according to the posture assumed by the patient to facilitate the work of the surgeon [1]

When these measures are employed, emphysema presents no problems in oxygenation or carbon-dioxide elimination, and spontaneous respiration is resumed quickly at the end of the anæsthetic if care has been taken to establish a light level of analgesia, hypnosis, and muscle relaxation.

LIPOPROTEIN PATTERNS IN MYOCARDIAL INFARCTION

SIR,—In reviewing the excellent article by Dr Elspeth B Smith [2] I was much impressed by the correlation between the characteristic lipoprotein band, the pre-β-lipid found associated with myocardial infarction, and the S_f20–100 part of the standard S_f12–400 class of lipoproteins of Gofman

In our attempts to reverse existing atherosclerosis and to lower the levels of both S_f0–12 and S_f12–400 lipoproteins, as well as cholesterol levels, it has been virtually impossible to lower the S_f20–100 and the S_f100–400 parts of the standard S_f12–400 class of lipoproteins without carefully screening out all products of hydrogenation.

Niacin (nicotinic acid), fresh thyroid extract, low-natural-saturated fats and low-cholesterol intake, plus 2–3 ounces daily of corn oil (mazola) or 12 capsules daily of 750 mg safflower oil by mouth, have been given to supply additional unsaturated linoleic acid. All products of hydrogenation were excluded, and replaced in all baked or fried foods by the essential unsaturated linoleic acid in the form of corn oil By this means it has been possible to reduce rapidly cholesterol and both groups of lipoproteins

Nicotinic acid was given in total daily dose of 3 g divided and after meals, and the fresh thyroid extract was started at usually no less than gr 3 and raised to gr 6 or more depending upon the lipid-lowering response

All our lipoprotein patterns were air-mailed the same day to the Gofman group at the Institute of Medical Physics at Belmont, California, for ultracentrifuge analysis, and all patterns are there recorded by number Dr Holly Heitzman, clinical director of St. Mary's Hospital, Green Bay, secured the blood samples for a portion of this study, and Dr John Ford, clinical director of St Vincent's Hospital, Green Bay, secured the remaining group of blood samples Both hospital groups are now correlating the total cholesterols, atherogenic indexes, and diastolic and systolic pressures

The following is a typical case, in which the intelligent cooperation of the patient was secured in this simple approach to the possible reversal of atherosclerosis

A 53-year-old woman weighing 163 lb had a blood sample taken on March 12, 1958 fasting cholesterol 200 mg per 100 ml , S_f0–12 413 mg per 100 ml , S_f12–400 844 mg per 100 ml , atherogenic index 189, blood-pressure 190 110 mm. Hg

On May 1 the findings were weight 146 lb , fasting cholesterol 140 mg per 100 ml , S_f0–12 245 mg per 100 ml , S_f12–400 62 mg per 100 ml , atherogenic index 35, blood-pressure 104 76 mm Hg

S.M.S. MEDICAL COLLEGE LIBRARY 2604

Of the utmost clinical significance during this study, which has been correlated with the Gofman group since November, 1957, has been the inability to produce any considerable lowering of the S_f12–400 class of lipoproteins without carefully screening out all products of hydrogenation.

At this point it definitely seems that the unnatural unsaturated fatty acids with a high melting-point, which are the products of hydrogenation, may be a most important factor and in all probability are not reflected in the total cholesterol estimation, and fall into S_f20–100 and the S_f100–400 parts of the standard S_f12–400 class of lipoproteins [3]. There is little doubt that a large part of human disease is due to physiological chemical imbalance, but it is apparent that the body cells can recover to an amazing degree from these chemical upsets.

Green Bay,
Wisconsin

WARREN T HAGERTY

THE ÆTIOLOGY OF LEUKÆMIA

SIR,—Your leading article of July 5 might be criticised on the grounds of incompleteness, but it would not be possible to meet this criticism in less than a large tome. It could be argued that the title was misleading and should have been the Virus Theory of Murine Tumours, and it is certainly odd to find no reference to, among American workers, Kaplan and Law and only one, purporting to support Gross, to Furth. However, accepting the thesis that Gross and Stewart and Friend have produced extremely powerful evidence in favour of viral agents being intimately involved in the development of various murine neoplastic diseases, or, as they might argue, causative, it must seem ludicrous to them to read your conclusions, (*a*) that an impasse has been reached, whereas in fact the field is developing so fast that even you, Sir, seem not to be abreast of recent multitudinous advances, and (*b*) that, an infective agent having now, you infer, been isolated and categorised, there is little that can be done about it. Oh, Koch!

J F LOUTIT

EXPERIMENTAL PRODUCTION OF ENDOMYOCARDIAL FIBROSIS

SIR,—I write to correct a statement attributed to me, by Professor Selye in his interesting paper [4].

I was quoted as saying that 40% of patients with heart-disease, admitted to hospital in Eastern Nigeria, have endomyocardial fibrosis. This statement was apparently based on my personal communication to Dr Brigden, to which reference was made in his St Cyres lecture [5].

What Brigden said was "Nwokolo has seen the condition (of endomyocardial fibrosis) in Eastern Nigeria, where he finds that 40% of cases of heart-disease admitted to hospital are cardiomyopathies." In that lecture, Brigden used the term cardiomyopathy to include obscure cardiopathies such as congenital cardiomyopathy, nutritional heart-disease, alcoholic heart-disease, amyloidosis, collagen diseases of the heart, infective myocarditis of all kinds, endomyocardial fibrosis, and other cardiopathies of unknown ætiology. It is clear therefore that Brigden did not use the term cardiomyopathy to mean endomyocardial fibrosis only, as Professor Selye's usage seems to imply.

In my communication to Dr Brigden, I referred in part to a publication [6] in which I reported cases of endomyocardial fibrosis confirmed at necropsy, as well as other cases in patients who died of congestive cardiac failure but in whom no fibrosis was found at necropsy. The figure of about 40% referred to the proportion of cases of obscure cardiopathies in relation to the total number of cardiac admissions into the General Hospital, Enugu, Eastern Nigeria, in a small series of cases.

My view is that endomyocardial fibrosis constitutes a mere fraction—probably under a third—of these obscure cardiopathies.

C NWOKOLO

CORTISONE IN THE TREATMENT OF ACUTE MILIARY TUBERCULOSIS

SIR,—I was pleased to read that Dr Lambros [1] has successfully treated a case of miliary tuberculosis using cortisone with the antituberculous drugs.

A case of miliary tuberculosis and meningitis in a patient who was also hypersensitive to streptomycin was included in a series of cases of active tuberculosis treated by corticotrophin and chemotherapy which I published in 1954 [2]. This patient remains completely well six years later.

Harefield Hospital,
Middlesex

L E HOUGHTON

ANKYLOSING SPONDYLITIS AND CHRONIC INTESTINAL INFLAMMATION

SIR,—Forestier [3] and Romanus [4] mentioned an association between ankylosing spondylitis and inflammatory intestinal disease, and Steinberg and Storey [5] have reported 6 cases. I have seen 3 examples of this association.

CASE 1.—A man, aged 31, was admitted to Frenchay Hospital in 1957. He had pain in the lumbar region and left leg, which had started some seven months previously and had been treated, by physiotherapy and a plaster-of-paris jacket, with improvement. He also had diarrhœa, which had started suddenly seven weeks previously, with bowel action 18–20 times daily, very loose, and frequently containing blood and slime. He had had previous episodes of diarrhœa in 1943 and 1944.

The left side of his abdomen was very tender, movements of the lower thoracic and lumbar spine were limited and straight leg raising was restricted on the left. Hæmoglobin was 54%, erythrocyte-sedimentation rate (E S R) 60 mm in the first hour (Wintrobe). Sigmoidoscopy showed a reddened mucosa but no ulceration in the rectum. A radiograph of the spine showed partial obliteration of the sacroiliac joints and some calcification in the anterior spinal ligament, this was regarded as typical of ankylosing spondylitis. A barium-enema examination showed very extensive changes involving almost all the large bowel, and these were typical of ulcerative colitis.

The patient improved on treatment with corticotrophin and was later given a course of radiotherapy to the spine after transfusion had corrected the anæmia.

Diagnosis.—Ankylosing spondylitis and ulcerative colitis.

CASE 2.—A man, aged 59, was admitted to Frenchay Hospital in 1954 complaining of loss of weight and pain in the back and neck of two years' duration. He was pale and wasted, and had considerable limitation of all spinal movements. Hæmoglobin was 70%, E S R 60 mm in the first hour, colour-index 1.3. The marrow showed a few megaloblasts but mainly a normoblastic picture. Stool examination showed definite steatorrhœa. Radiographs of the spine showed fusion of both sacroiliac joints and calcification of the spinal ligaments. Barium-enema examination showed no definite abnormality.

He made good response to treatment with folic acid, iron, and calciferol, and his hæmoglobin rose to 94%. He was later given a course of radiotherapy which eased his spinal pain considerably

[5] Steinberg, V L, Storey, G *Brit med J* 1957, ii, 1157

Diagnosis —Ankylosing spondylitis and steatorrhœa of unknown cause

CASE 3 —A man, aged 53, was admitted in 1957 to Southmead Hospital for investigation of bouts of diarrhœa which had begun three years previously The motions were at times very offensive and contained blood and mucus He had been under treatment for ankylosing spondylitis since 1946

Spinal movements were much limited and occult blood was present in the fæces Hæmoglobin was 84%, E S R 46 mm in the first hour Radiographs of the spine showed bridging between the bodies of the lumbar vertebræ Barium-meal and follow-through examination showed a definite irregularity of the terminal ileum, of the type seen in regional ileitis

His diarrhœa settled when codeine was given orally, and his general condition improved in hospital

Diagnosis —Ankylosing spondylitis and Crohn's disease

In these 3 cases, chronic intestinal disease was associated with ankylosing spondylitis, and it is my impression that this association is not one of chance

I should like to thank Dr J M. Naish for permission to publish these cases

Frenchay Hospital, Bristol

S G FLAVELL MATTS

THE TOURNIQUET

SIR,—In your leading article of May 31 and in Professor Pannett's letters of March 15 and June 14, certain categorical condemnations of the tourniquet are made While it is true that there is an increasing tendency for limb surgery to be undertaken without the tourniquet, the time has not yet come when it could or should be completely discarded

Professor Pannett's experiences of " enormous œdema when the tourniquet is removed " and his view that " infection is likely to establish itself more easily " are not paralleled by the experience and opinions of many orthopædic surgeons It is possible, for example, to use below-knee tourniquets for foot operations with full hæmostasis but without getting peroneal palsies if the " Esmarch's " bandage is accurately applied Infection of clean wounds is rare in orthopædics and is no commoner in, for instance, knee operations done with a tourniquet than in hip operations done without Again, postoperative œdema need not follow, particularly if the surgeon himself puts on the bandages, not leaving it to the most junior person in the theatre

While I entirely agree with your reiterated warnings on the use of the tourniquet, I cannot agree with ex-cathedra pronouncements (such as " There is no place for below-knee tourniquets ") which can only cause embarrassment to some and give universal condemnation to a procedure which continues to have a place in the right hands

Mr I S Smillie once said, in reply to a charge that one of his instruments was dangerous " All surgical instruments are dangerous unless they are used properly " The same applies to the tourniquet

Canterbury

F G ST CLAIR STRANGE

RECORD OF EXPOSURE TO RADIATION

SIR,—At the present rate of nuclear-weapon tests we shall soon have reached the point of no return as far as the limit of safety to radiation exposure is concerned This is a grim state of affairs about which the medical profession can do little more than indicate the risks and dangers

We have, however, a grave responsibility in deciding whether our patients should be exposed to further radiation in the form of diagnostic X rays I have for long been concerned at the casual way in which these investigations are carried out, usually with no regard to the number and cost of films taken in the past and often with insufficient consideration to the question " is this procedure really necessary ?"

It seems to me that the time has now arrived when every patient should have some sort of simple record card whereon is shown the total amount, as far as it can be estimated, of previous radiation to which he has been exposed and where can be recorded subsequent amounts at the time the films are taken

Shrewsbury

A W J HOUGHTON

INFLUENCE OF LIGHT ON THE HYPERBILIRUBINÆMIA OF INFANTS

SIR,—I was very interested in the paper on the above subject by Dr Cremer and his colleagues,[1] and their effort to use light for the reduction of hyperbilirubinæmia Their observation that serum-bilirubin is photosensitive was also noted by me and recorded, in a paper on the Technique and Interpretation of the van den Bergh Test, in the *Irish Journal of Medical Science* for September–October, 1927, when I said. " Sera to be examined should not be exposed to bright sunshine "

Dublin

R E STEEN

CERVICAL AORTIC ARCH

SIR,—It would seem desirable to make a plea against the term " cervical aortic knuckle " to describe the aortic-arch anomaly noted by Professor Lewis and his colleagues [2]

It is the summit of the arch itself which is seen pulsating in the neck, whilst " knuckle " might imply an aneurysmal dilatation of the arch which projects The term is undesirable also in that it carries an ætiological suggestion of the aortic arch having spilled or " knuckled " out of the chest Embryological considerations refute this possibility and show that the arch is, in these cases, a cervical structure

In January, 1957, a 35-year-old certified mental-defective man, having a right upper mediastinal shadow on a mass radiograph, associated with a pulsatile swelling on the right side of the neck extending to the hyoid cartilage, was admitted to hospital Compression of the mass produced obliteration of pulses in the right arm and both femoral arteries, whilst those in the left arm remained Manometric tracing of this diagnostic obliteration of femoral pulse was obtained, and the anatomical features of the convoluted, right-sided aortic arch in the neck were demonstrated by retrograde aortography These appearances differed from the post-mortem findings of Beavan and Fatti [3] in that the left subclavian artery arose from a left innominate artery, the first branch of the arch, whilst in their case the left subclavian was the last major branch of the arch No evidence of dyspnœa nor dysphagia could be obtained and the patient remains under observation This case was presented with cine-photography of the swelling by Mr R Abbey Smith at the summer meeting of the Thoracic Society in 1957 and a detailed report and analysis are being prepared

It should be remarked that in all three patients noted to have this condition, the cervical aortic arch has been right-sided, and the descending aorta left-sided Reid [4] described an anatomical dissection in which a right aortic arch " ascends through the superior aperture of the thorax into the root of the neck and must have given rise to marked supersternal pulsation "

---

1 Cremer R. J , Perryman P W , Richards, D H. *Lancet*, 1958, i, 1094
2 Lewis, C , Harley, H R. S Rogers L C. *Lancet* 1958, i, 1340
3 Beavan T E D , Fatti, L *Brit J Surg* 1947, 34, 414
4 Reid, D G *J Anat , Lond* 1914 48, 174

Notably, also, the cases of abnormally high thoracic aortic arch recorded by Tori[5] and Mr Norman Barrett's case[6] have been right-sided The embryological grounds for this right-sided nature are perhaps less readily acceptable than the reasons for a cervical arch, and it is noteworthy that, in the offspring of vitamin-A-deficient rats, Wilson and Warkany[7] found the condition twice on the left, three times in a double aortic arch, but never singly on the right, though in all cases there were also other variations of the arch pattern Nevertheless, and at least until a left-sided case is recorded, it seems reasonable to describe the condition now recognised as "right-sided cervical aortic arch"

Dysphagia developing for the first time in middle age owing to ring-like formation raises particular consideration in these cases Both dysphagia and dyspnœa may present during infancy from vascular rings Dysphagia, without dyspnœa, developing for the first time in adult life, usually middle age, is considered to be due to degenerative changes in the wall of the systemic vessel, and is most commonly associated with retro-œsophageal arteries rather than vascular rings Should this symptom develop then in a case of right-sided cervical aortic arch, the possibility must also be considered that it is due to atheromatous changes in the retro-œsophageal descending part of the aorta—especially when, as in our case, a left-sided ligamentum arteriosum, if present, is probably long and anterior—rather than a ring formation

Obituary

ANDRIJA STAMPAR

M D Vienna

FROM Balkan peasant to first chairman of the Economic and Social Council of the United Nations and president of the first Assembly of the World Health Organisation—such was the record of Andrija Stampar Like most other men who have made their mark in international health, he first achieved prominence through hard work and advanced ideas in his own country

Born in 1888 in Croatia, he qualified at Vienna in 1911 and from the beginning showed his abiding interest in social medicine He wrote and lectured against the evils of alcoholism, and he remained a lifelong teetotaller After working as a district medical officer in Croatia, he became in 1919 director of public health for the whole of the new kingdom of Yugoslavia in his early thirties and introduced many reforms into the organisation and practice of rural hygiene In 1931 he returned as professor of hygiene to Zagreb, where a school of public health had been founded with the help of the Rockefeller Foundation The essence of his teaching was a two-way traffic by which leading villagers came to the school to be taught simple principles which they put into practice on returning home Such ideas are almost commonplace in underdeveloped rural communities nowadays, but they are only commonplace because of Stampar's initiative and drive

Dr Rajchman, director of the Health Organisation of the League of Nations, was among the first to recognise Stampar's work and worth and secured his help for the Health Organisation in various ways, including membership of the Health Committee of the League He served the League in China from 1933 to 1936 and visited the United States and this country on many occasions The war—and Stampar's Left-wing views—led to his internment in Austria for a time, but liberation found h beloved Zagreb University, of which he was made recto intact if impoverished, and he obtained many supplie and books from friends and sympathisers in this and othe countries

Unique among Yugoslavs at that time in his pre-wa international experience and reputation, he was quickl restored to even greater international prominence an elected chairman of Ecosoc which, at its first meeting i 1946, acted on the decision of the San Francisco conferenc that an international conference should be called t consider setting up an international health organisation o the United Nations

Stampar served on the technical preparatory committe for this international health conference and submitted memorandum on the constitution of the new agency besides taking part in the conference itself It was therefor wholly appropriate that he should have been electe chairman of the Interim Commission of W H O in 19 and president of its first Assembly in 1948 Since tha time until recently he had been associated with the worl of W H O in many ways, and in 1955 he received th Leon Bernard Foundation prize for pre-eminent work i social medicine

A colleague writes

Stampar's success had three elements—technical competence, political flair, and a peasant toughness which, in the polit world of international health, made men chary of offendin him His very appearance inspired a certain awe His cannon-ball head, sunk between huge shoulders, looked as if he coul batter a breach in a wall with it—sometimes indeed he migh have tried to do so to judge from his temper when things had not gone as he wanted! It needed courage, as well as affection, for the chief British delegate to take him by the arm on one such occasion and remark, "Well, you great Balkan bear! How's the sore head this morning?" But all in all he was a great man and his country should be proud of him

Appointments

DEWAR, A E, M B St And, F F R, D M R D assistant radiologist, X-ray diagnostic department, St Thomas's Hospital, London

FRANKLAND A W, D M Oxon part-time consultant in charge of the clinic for allergic disorders (Wright Fleming Institute of Microbiology), St Mary's Hospital, London

HALL, THOMAS M B Cantab assistant M O, Wembley and Willesden

MCEVEDY, B V, M CH Oxon, F R C S assistant surgeon, Royal Victoria Infirmary, Newcastle upon Tyne, and surgeon, Gateshead hospital group

MACINTYRE, J C, M B Glasg, D A S H M O in anæsthetics, Stornoway hospitals

RHODES, PHILIP, M B Cantab, F R C S, M R C O G part time consultant in obstetrics and gynæcology, St Thomas's Hospital and Lambeth Hospital, London

*WILD, A A, M B Edin, D M R D full time consultant in radiology York A and Tadcaster, Scarborough, Bridlington, Malton and Whitby hospital groups

Birmingham Regional Hospital Board

DUNCAN, J McK, M B Birm, F R C S part-time consultant surgeon, Dudley and Stourbridge hospital group

HOOPER, B R S, M B Lond, F F A R C S, D A part time consultant anæsthetist, Lichfield, Sutton Coldfield, and Tamworth hospital group

KALRA, P L, M B Birm, D P M assistant psychiatrist, St George's Hospital Stafford

PORTER, K R D, M B E, M R C S, D P H deputy senior administrative M O to the board

Manchester Regional Hospital Board

ALLEN, W M, M B Manc, D M R D consultant radiologist, Preston and Chorley hospital group

LEWARS, P H D, M B Durh, B D S senior hospital dental officer, South Manchester hospitals

MARTIN, W M, M B Belf assistant anæsthetist, Burnley and district hospital group

* Amended notice

Notes and News

EXTENSION TO BIRMINGHAM MENTAL HOSPITAL

ON June 26 Dame Enid Russell-Smith, deputy secretary of the Ministry of Health, opened two 40-bed pavilions at Hollymoor Hospital, near Birmingham.

The new buildings, which are about a quarter of a mile from the main buildings, stand on a southern slope, and have been designed on one floor so that the open outlook from the hospital is unimpaired The two units are linked by a kitchen with its own service entry The dayrooms and dining rooms of each unit are next to the kitchen They have low window sills to make the best use of their southern aspect and view of the Lickey Hills, and open fireplaces of natural clipsham stone Each unit has two 20-bed dormitories linked by sanitary wings which are also accessible from the day rooms Light, cheerful colours have been used for walls, door, and curtains, neutral shades for the rubber floors, rugs, and furniture The scheme was designed by S N Cooke and Partners in association with Mr D A Goldfinch, architect to the Birmingham Regional Hospital Board

After the opening ceremony plaques were unveiled commemorating the work of Dr S J Scurlock, who has lately retired from the post of senior administrative medical officer of the Birmingham regional hospital board, and of Dr T A. Lambo, psychiatrist to the Aro Hospital in Western Nigeria, who is cooperating with the hospital in the training of Nigerian student nurses

ECONOMY IN PRESCRIBING

THE Ministry of Health has accepted the view, expressed in the interim report of the Committee on the Cost of Prescribing,[1] that the supply by executive councils of medical and pharmaceutical lists to drug houses is undesirable The Ministry has asked any executive councils that hitherto have provided lists in this way to discontinue the practice.

University of Manchester

At recent examinations the following were successful

University of Sheffield

Mr A. W. Kay, lecturer in surgery in the University of Glasgow, has been appointed to the chair of surgery in succession to Prof R. P Jepson.

Mr Kay, who is 41 years of age, graduated M.B with honours from the University of Glasgow in 1939 After holding house-appointments in Glasgow at the Western Infirmary and the Royal Hospital for Sick Children, he was appointed in 1941 a Hall tutorial fellow and clinical assistant at the Western Infirmary In 1942 he took the F.R.C.S.E. and in 1944 he received the degree of M.D with honours and was awarded the Bellahouston medal. In 1945 he was appointed assistant in the department of surgery at Glasgow University and surgeon to outpatients at the Western Infirmary After two years as a major in the R.A.M C., when he was in charge of the surgical division at Millbank Military Hospital, he returned to Glasgow as consultant surgeon to the Western Infirmary and honorary lecturer in surgery at the university In 1949 he took the CH.M. with honours In 1955 he became first assistant to Prof. C. F W Illingworth, and he was appointed to his present lectureship in 1956 He has also been surgeon in charge of wards at the Western Infirmary since 1956 He is a member of the Medical Research Council's external scientific staff. He was elected F.R.F.P.S in 1956. Mr Kay is co-author of a textbook of surgical physiology which is in the press, and his published work includes a paper on the augmented histamine test.

Royal College of Surgeons of England

On July 3, Mr Eric Riches and Sir Arthur Porritt were re-elected, and Mr. F W Holdsworth and Mr J Cridlan Barrett were elected members of the council

Order of St. John of Jerusalem

The Queen has sanctioned the following promotions in, and appointments to, this order

As Knights —Colonel F A Bearn, C B E, D S O, M C, M D, H S Taylor-Young, F R C S

As Commanders —Major-General A E Campbell, C B, M D, Q H P, Colonel Malcolm MacEwan, D S O, O B E, D F C, T D, M B, Surgeon Rear-Admiral D M Beaton, O B E, L R C P E, Q H P, Surgeon Rear Admiral D F Walsh, O B E, F R C S E, E C Brewis, M D, T W A Gray, M D, Colonel G E Wight, O B E, M D, Elsie C Hanson, M D

As Officers —Major-General T F M Woods, O B E, M D, Q H P, Lieut-Colonel D H D Burbridge, M R C S, J B Dobson, F R C S, A D Griffith, L M S S A, Archibald Russell, M B, D P Kennedy, E D, M B, J G Stewart, M C, M B, T H Pullar, M R C P, James Moffat, M B, W A Hogg, M B, H J Hoby, M R C S, L S Potter, M B, Colonel Geoffrey Anderton, O B E, M B, F L Fletcher, M R C P, J W Pickles, M B, C D Short, M D, Brigadier C S Thompson, O B E, M D, M G Townsend, M D, Marguerite F E Wylie, M R C S

Society of Apothecaries of London

On July 22, at 8 30 P M at the hall of this society, Black Friars Lane, E C 4, the Master will confer the honorary freedom of the society on Sir Henry Souttar and bestow the Galen medal on Sir Macfarlane Burnet

Royal Society of Medicine

The following officers have been elected for 1958–59

President, Sir Geoffrey Marshall, immediate past president, Sir Clement Price Thomas, hon treasurers, Mr E G Muir and Dr Basil Kiernander, hon secretaries, Mr Terence Cawthorne and Prof R H S Thompson, hon librarians, Prof C G Rob and Dr J S Richardson, hon editors, Dr E C Warner and Mr Selwyn Taylor, hon directors of photography, Mr Myles Formby and Dr F C Kelly

Institute of Diseases of the Chest, London

Clinical demonstrations, open to doctors without fee, will be continued at this institute (in the grounds of the Brompton Hospital, Fulham Road, S W 3) on Fridays at 5 P M throughout the summer

Royal Society

With awards from the society's Nuffield Foundation Commonwealth bursaries scheme, Prof T Gilman (Natal) is to study skin regeneration at University College, London, and Dr T B Teoh (Hong Kong) bile thrombi at University College Hospital Medical School

Royal Medical Benevolent Fund

The annual general meeting of this Fund is to be held on Wednesday, July 30, at 5 P M at 11, Chandos Street, London, W 1

Anglo-French Bursaries

Awards have been made for work in France in 1958 under the exchange arranged by the Institut National d'Hygiène, Paris, and the Ciba Foundation, London, to Dr Evan Fletcher, Dr J G Howard, Dr E M Jepson, Mr J F O Mitchell, and Dr P M Peacock

Harveian Society of London

Members of this society on June 22 attended a service at Hempstead Church, Essex, where William Harvey is buried Lessons were read by Dr D A Imrie, president of the society, and Mr A Dickson Wright, president of the Harvey Tercentenary Congress, and the Bishop of Colchester preached the sermon The appeal fund for restoration of the church tower has now reached over £3000

International Congress of Psychotherapy

This congress will be held in Barcelona from Sept 1 to 7 Application to take part should be made to the secretary, Catedra de Psiquiatria de la Facultad de Medicina, Casanova 143, Barcelona There will be a special section on psychopharmacology, details of which may be had from Prof F G Valdecasas, department of pharmacology of the faculty Applications must be submitted not later than July 31

British Association of Paediatric Surgeons

This association will hold its annual meeting in London from *Wednesday, July 23, to Friday, July 25*

International Congress on Nutrition

This congress will be held in Washington from Sept 1 to 7, 1960 Further particulars may be had from Dr M O Lee 9650, Wisconsin Avenue, Washington 14, D C, U S A

Health Services Whitley Council

The council have appointed Sir William Matthews, a forme under-secretary at the Treasury, and Mr R E Peers, assistan secretary of King Edward's Hospital Fund for London, to joi Sir Noel Hall *on a committee to compare the wages of Nationa* Health Service workers with those of people in similar employment

Changes in the Prescribed Diseases Schedule

The Minister of Pensions and National Insurance has made regulations (S I 1958, no 1068) altering the schedule of occupational diseases for which workers are covered for the benefits of the Industrial Injuries Act The regulations implement the recent recommendations of the Industrial Injuries Advisory Council (see *Lancet*, 1958, i, 906)

Progress in the Biological Sciences in Relation to Dermatology

A course on this subject will be held by the University of Cambridge Postgraduate Medical School from Sept 22 to 27

It will consist of half-day sessions, each devoted to a group of papers on the same or related subjects, including the melanocyte and melanogenesis, cutaneous innervation, the histochemical investigation of the skin, bacteriology, psychophysiological mechanisms, comparative medicine, immunology, inflammation, carcinogenesis, radiation of the skin, and pharmacology The course is designed for dermatologists but is open to any doctor interested in the subjects under discussion Accommodation and board will be provided in Downing College Further particulars may be had from the secretary of the Medical School, Tennis Court Road, Cambridge

---

On July 3 at the Middlesex Hospital Medical School Lord Astor of Hever presented the Comfort Crookshank medal to Prof Charles Huggins of Chicago

List of Films on Human Anatomy and Embryology —In preparing the second edition of this world list Dr R Brouwer has found it necessary to limit the number of films selected Some films showing the anatomy or embryology of animals have been omitted, but others *dealing with human anatomy* and embryology have been added Copies (£1) are available from the Netherlands Scientific Film Association, Catharijnesingel 59, Ingang Sterrenbos, *Utrecht*, Holland

PROGRESS IN THE CONTROL AND REDUCTION OF LEPROSY

Sir Leonard Rogers
K.C.S.I., M.D. Lond., LL.D. Glasg., F.R.C.P., F.R.C.S., F.R.S.

As the result of several years' research in Calcutta, I was able to record in 1917 that a number of fairly early cases of leprosy had been cleared of active symptoms by injection of a new soluble hydnocarpate of soda, which replaced the ineffective and nauseating oral administration of chaulmoogra oils (Rogers 1918). Up to that time the only plan in common use for controlling leprosy was the centuries-old compulsory segregation for life of all discovered cases. This drastic measure—unknown in modern times in the case of any other such chronic disease—had failed repeatedly to achieve its avowed purpose.

After my retirement from India I devoted three years to a comprehensive study of the previous fifty years' literature of leprosy (Rogers 1922) and formulated a plan of control (Rogers and Muir 1925–46).

Principles

Compulsory segregation failed because it led to the hiding of patients in South Africa and the Philippines, where it was most rigidly enforced, cases were not notified until seven to nine years after the first appearance of symptoms. During this time of hiding they had infected members of their households and other close contacts, who carried on the disease indefinitely.

Moreover I obtained evidence that only a fifth to a fourth of all the cases were highly infectious—namely, the mucocutaneous type (to use the old but more descriptive term rather than the indefinite "lepromatous", which has come into use). Their infectivity is due to their sneezing and coughing myriads of lepra bacilli from their infected mucous membranes over highly susceptible and lightly clothed children of their households in humid, hot, insect-infested regions which constitute nearly all the areas of high incidence of leprosy (Rogers 1923). As the earliest symptoms of leprosy are found on exposed parts of the body, punctures of the skin by insects and abrasions afford entry for the bacilli, although the evidence is against direct inoculation by contaminated insects.

For these and other reasons I laid down the following principles of prophylaxis, which were adopted by the British Leprosy Relief Association (BELRA) shortly after its foundation in 1924, and have ever since been advocated by it.

(1) *Surveys of people in samples of leprosy-infected countries to determine extent of leprosy.*—The necessity for this measure is clearly shown by the fact that in India Muir found the true number of cases to be eight times the official ten-yearly census figures. A similar survey revealed the very unexpected number of 400,000 cases in Nigeria and 254,000 in British East Africa (Rogers 1955).

(2) *Only highly infectious mucocutaneous cases are in urgent need of isolation to stop new infections.*—The economic importance of this principle will be clear from the experience of South Africa (Rogers and Muir 1946, Rogers 1954). In that country segregation for life of all discovered leprosy patients has been enforced since 1892 without even preventing a steady increase of the disease due to hiding of the cases to avoid lifelong imprisonment without hope of successful treatment. But, when the value of hydnocarpate injections in early cases became known, patients in the early stages flocked voluntarily into the leprosarium for treatment. The medical authorities thought it necessary to continue compulsory segregation for all active cases because the disease was scattered over an immense area, but patients without active symptoms, chiefly with chronic neural leprosy, were released. The average duration of symptoms on admission fell from seven to two or three years, and the incidence of leprosy fell from 2.21 to 0.77 per 1000 by 1953. This notable success was obtained at a cost in some years of £250,000, or £100 per patient per annum; this only a gold-producing country could afford. But the accompanying table shows that over 700,000 cases require treatment in British tropical African territories compared to an average of less than 2500 under segregation in South Africa.

(3) *Voluntary isolation of all infective patients in special villages at very low cost.*—Soon after BELRA was founded, Lord Lugard, formerly Governor of Nigeria, told me that in South-East Nigeria it had been customary to isolate advanced cases of leprosy in special villages in which no uninfected people were allowed to reside. I therefore decided to revive this custom as the only economical plan of isolating the highly infective cases. This was later borne out by surveys revealing an estimate of 177,722 unisolated infective cases in British tropical African territories. Yet the recently constructed leprosarium in East Africa, with an attached research laboratory, cost BELRA alone £27,000 in capital and £4000 annually in upkeep.

(4) *Three-yearly surveys of contacts to detect newly developing cases in earliest easily curable stage.*—The necessity for this additional—and, I believe, previously unused—precaution may be illustrated by T. F. Davey's statement to me that on the third such survey of a tribe 7000 strong in South-East Nigeria, although not a single infective case was found, no less than 40 persons were discovered with very early symptoms which had appeared since the last survey. Such cases can now quickly be cleared up whereas formerly they would have become infective—probably long before they were segregated.

Trials of New Plan of Reducing Leprosy Incidence

Small-scale Trial in Nauru Island, Australia, in 1925

After consulting me, the Australian medical authorities made a survey of the small indigenous population of Nauru and found that nearly 30% showed signs of leprosy. Of the patients thus discovered, 90% were in a very early stage of the disease, but there were also some highly infectious cases. My plan was put into operation, and three years later Bray (1930) reported that the number of cases had been reduced by 40%. In 1934 Grant recorded a reduction by 66%. Moreover scarcely any of the early cases had gone on to reach an infective stage. Eighteen years later Wade and Ledowsky (1952) found only a seventh of the earlier numbers. The latest report, in 1957, shows only 47 cases, or 2.8 per 1000, of whom only 9 were isolated as infective.

INCIDENCE AND CONTROL OF LEPROSY IN BRITISH TROPICAL AFRICAN TERRITORIES

Territory	Known and estimated total cases						Infective cases				
	Population	Known cases under treatment	Estimated unknown and untreated cases	Total of known and estimated cases	Total cases per 1000 of population	Percentage of total cases under treatment	Infective cases isolated and treated	Infective cases unisolated and untreated	Total known and estimated infective cases	Percentage of infective cases isolated and treated	Estimated yearly cases infected from unisolated cases
Eastern Nigeria	8,000,000	28,237	54,000	82,237	10 3	34 3	15,572	5428	21,000	74 2	1084
Western Nigeria	6,000,000	8268	61,000	69,245	11 5	11 9	5242	12,058	17,300	30 3	2411
Northern Nigeria	16,800,000	17,266	250,000	267,266	15 9	6 5	11,310	55,390	66,700	17 0	11,078
East Africa	15,272,784	16,446	203,450	219,890	14 4	7 5	11,666	92,734	104,400	11 2	18,572
Gold Coast	5,000,000	14,860	50,000	64,860	13 0	22 9	860	12,112	12,972	6 6	2422
Total	51,072,784	85,077	618,450	703,498	13 8	12 1	44,650	177,722	222,372	20 0	35,567

Control Measures in Hyperendemic Areas of Tropical Africa

In 1923 I published a map of the world to show that nearly all the highest incidences of leprosy are met with in hot humid tropical and subtropical climates with annual rainfalls of 30–60 in or more, especially in Africa, where later surveys showed that 86% of the leprosy patients for whom the British are responsible are found This led **Belra** to concentrate its main efforts on that hyperendemic region

Progress in the control of leprosy in the British Commonwealth has been recorded (Rogers 1954, 1955), and the present position in tropical Africa is illustrated by the comprehensive data in the accompanying table

The estimated yearly new infections from unisolated cases were estimated at a yearly rate of one child for every five highly infective cases in their households This I regard as a conservative estimate in view of the fact that early cases are nearly always found in households containing an active mucocutaneous case

The table shows that the rates per 1000 population vary between 10 3 and 15 9 in British tropical African areas Yet those of 96 countries I worked out for three editions of *Leprosy* (Rogers and Muir 1925–1946) and later unrecorded ones show no such high incidence in extensive areas with high populations For example, India in 1941 showed a rate of only 3 4 in spite of the number of cases having been estimated by surveys at eight times the census figure

Nigeria presents the greatest leprosy problem in the world, with an estimate of 418,748 cases (see table) East African areas come a good second, with 219,890 in Uganda, Tanganyika, and Nyasaland, apart from Kenya, where suitable data are not available The Gold Coast has an estimated number of 64,860 cases, making a grand total of 703,498 in the areas under consideration—about three-quarters of the probable total cases in British territories all over the world, after allowance has been made for underestimates in those of them which have not yet made surveys to determine the true numbers (Rogers 1954)

Belra has concentrated on control measures of different degree according to local facilities as the most urgent task, beginning first in Eastern Nigeria, where alone it has maintained them long enough to produce material results, but also to a less extent in Western Nigeria, and only for the last few years in Northern Nigeria

East Africa presents a difficult problem because the cases are scattered over a million square miles of territory It was found advisable to contribute largely toward the cost of construction of a large leprosarium for 1000 infective cases, with a research laboratory

In the Gold Coast it is only quite recently that vigorous efforts have been made to supply treatment to as many cases as possible at clinics situated at intervals of 10–15 miles along all the main and most of the subsidiary roads by a staff on bicycles over a territory of 91,000 square miles—all until recently under control of a single medical officer, Dr A Mackelvie By this means 14,860 cases, or about 23% of the total estimated cases, are receiving regular treatment and many of them prevented from developing into a highly infectious stage

That experience emphasises the importance of supplying a whole-time officer to take charge of leprosy-relief measures in any extensively infected area **Belra** has several times initiated such measures by offering to find half the salary of such a specialist medical man for a term of years

Returning to the data of the three divisions of Nigeria we find that the progress made in the proportion of cases under treatment and the proportion of infective cases isolated and treated, and consequently the degree of control supplied, increases with the length of time during which the control measures have been applied Thus the figures are highest (34 3% and 74 2% respectively) in Eastern Nigeria and lowest (6 5% and 17 0% respectively) in the Northern Division Western Nigeria shows intermediate figures (11 5% and 30 3% respectively) but has the second highest figure of the whole table of infective cases isolated and treated We must therefore turn to the work in Eastern Nigeria for evidence of any material reduction of the incidence of leprosy due to the modern measures of control

Evidence of Material Reduction of Leprosy Incidence in Eastern Nigeria within Two Decades

When, as a result of the success of the small-scale leprosy-control measures in Nauru Island (see above) it was decided to conduct a large-scale trial in the Eastern Nigerian hyperendemic area, it was fortunate that the help of two successive medical missionaries was available The economical village system of isolation was first introduced for the isolation and treatment of infective cases by J A Kinnear Brown (personal communication) His health broke down—although subsequently he was able to start the same measure in Uganda, and he was succeeded by T F Davey, who made careful surveys of all the people in different groups and repeated such surveys from time to time Only a brief summary of his results (Davey et al 1956) can be given here

No less than 302 special isolation villages were constructed, "often at negligible cost and with the cooperation of the entire community" In one instance repeated surveys disclosed a reduction of leprosy from 31 to only 5 per 1000 in the eight years 1943–51 In another clan the disease almost completely died out within ten years Many patients with tuberculoid leprosy were discharged in an inactive condition, but lepromatous cases rarely cleared up and then only slowly Unstable "indeterminate" cases treated with hydnocarpus oil rarely degenerated into lepromatous leprosy Through its action on such patients in particular hydnocarpus oil must have contributed to the decline of leprosy In this and contemporary trials striking results were recorded before sulphones became the standard treatment in Eastern Nigeria in 1951 in the form of oral dapsone Davey et al (1956) record that during the past six years a mass of evidence has accumulated of a decline in the incidence of the disease that is widespread and it is gaining in momentum each year Thus, whereas in three provinces 30,630 patients with active leprosy were receiving treatment in December, 1948, by the end of 1954 the number had dropped to 14,770, a decline of 50% Davey et al discuss other possible causes of the great decline and conclude that they could have produced no such profound effects in the space of seven years Moreover, during the last fifteen years about 30,000 patients, including most of the infective ones, have been isolated for longer or shorter periods in local segregation villages Evidently the intense and widespread work for the control of leprosy has been of great importance in Eastern Nigeria

Present Position of Sulphone Treatment of Leprosy

The discovery (by American leprologists at the Carville leprosarium in Louisiana) that sulphones are efficacious against leprosy is undoubtedly the greatest advance in the history of the disease Lowe (1950), working for BELRA in Eastern Nigeria, was able to demonstrate the value of oral administration of the more economical mother sulphone dapsone, which could be used more easily on a large scale The most important property of the sulphones is their effect in healing the lesions of the nose, throat, and larynx, and ulcerating nodes, and very greatly reducing their infectivity

There remains the serious difficulty of getting rid of the immense numbers of lepra bacilli in the nodules Sweetes (1955) records that, after three years' sulphone treatment of 800 lepromatous cases, in only 11% had the patient's tissues been freed from the bacilli American leprologists therefore think it necessary to continue the treatment of such cases for years at great total cost

Personally I very much doubt whether the comparatively few bacilli remaining deeply situated in subcutaneous nodules are likely to escape from the body in numbers constituting any material danger to other people I therefore advise that, whenever numerous untreated and far more highly infectious cases are awaiting isolation, nearly cleared patients should be discharged from isolation to attend clinics and be bacteriologically examined from time to time for signs of relapse

Further research for active drugs to supplement the sulphones is needed and is being pursued Thus BELRA has originated and is financing such work in both West and East Africa Any advances that may be made will bring nearer the day when leprosy will be virtually eliminated from the worst-infected areas of the world, by the measures so long advocated by me and now proved effective in the hyperendemic region of Eastern Nigeria

Summary and Conclusions

A plan formulated in the 1920s for reducing the incidence of leprosy proved highly successful on a small scale in the island of Nauru

The British Leprosy Relief Association, founded in 1924, helped to finance during two decades a large-scale trial of the new methods in highly infected Eastern Nigeria As a result the incidence of leprosy there was materially reduced

In the 1940s American leprologists discovered a new and potent remedy (especially in infective mucocutaneous, or lepromatous leprosy) in the sulphones By the beginning of the present decade further researches in Nigeria had led to the simple and effective use orally of the mother sulphone, now known as dapsone

Recent surveys in British tropical African territories have produced the estimated figure of 703,498 cases of leprosy, of which 85,000 (12%) are being treated in several hundred outpatient clinics, and 44,656 highly infective cases are isolated with treatment in three hundred special villages constructed for them at very low cost compared with large segregation settlements Moreover, some promising new drugs have been tested in the research laboratories of West and East Africa to supplement the sulphones

The way has thus been prepared for the steady reduction in the incidence of the ancient scourge of leprosy, probably nearly to the point of eradication—if only the essential additional staff and funds are forthcoming

THE fabulously rich State of Kuwait exported some 56 million tons of oil last year There is promise of a higher annual yield Already, however, 230–240 tankers (and 14,000 or so sailors) call *each month* at Kuwait's Mina-al-Ahmadi (fig 1) to load oil for world markets In June, July, August, and September of each year this operation is carried out in environmental shade temperatures of 95–120°F (35–49°C) dry-bulb and 60–90°F (15–32°C) wet-bulb Midsummer sun temperatures may exceed 160°F (71°C) In such circumstances the occurrence of heat casualties is not surprising

The crews of ships sailing in the Red Sea, Gulf of Aden, and Persian Gulf have never been exempt from the effects of heat Cases aboard Naval vessels in these and neighbouring waters have been described in recent years by McLean (1943), Stenning (1945), Thomson (1946) and Crowden (1951) Ellis (1955) considered that unreported heat effects had a serious impact upon the Fleet during the second world war

We report here 128 cases of heat illness arising in the summer months of 1956 and 1957 among personnel of

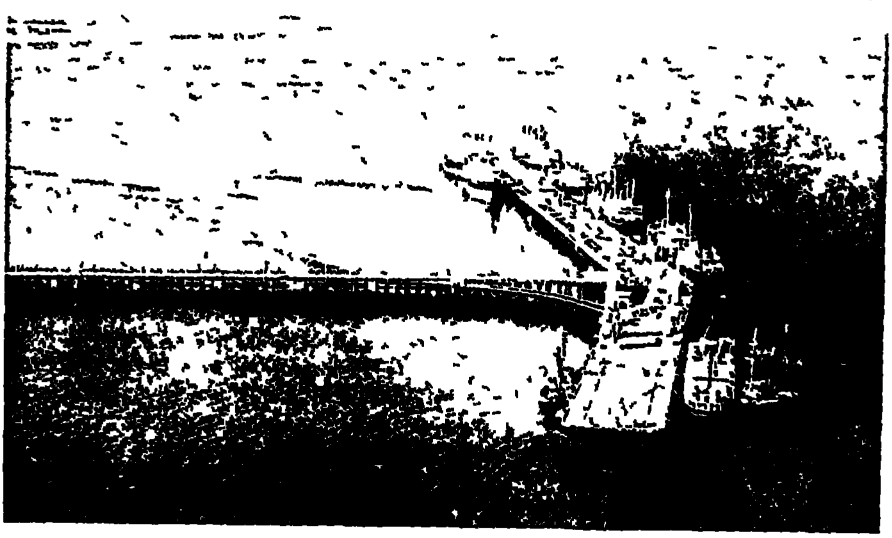

Fig 1—Oil pier, Mina-al-Ahmadi

oil-tankers sailing in the Persian Gulf and calling at Mina-al-Ahmadi

Patients and Methods

The pier at Mina-al-Ahmadi is provided with a clinic and heatstroke treatment room where the patients were first seen by the duty quarantine medical officer (Kuwait State health department) For further investigation and treatment, some patients were admitted to the Kuwait Oil Company hospital at Magwa, 15 miles inland

Clinical impressions were augmented by estimations of chloride content of urine, whole blood, and plasma, sodium and potassium levels of whole blood and plasma, blood-urea level, and plasma specific gravity (methods after King 1951) Urine samples were first screened by the Fantus (1936) technique, and urine found to contain less than 3 g of chloride per litre was further examined by the Volhard titration method

The investigations were supported by a survey of acclimatisation and health of British, American, Arab, and Indian residents ashore, in the Kuwait Oil Company town of Ahmadi

Environmental temperatures—e g, in ship compartments—were measured with a sling hygrometer, and air movement with a katathermometer Coastal temperatures in fig 2 were derived from the Kuwait Oil Company marine department's meteorology station at Mina-al-Ahmadi, where the thermometers were mounted in a Stevenson screen

Incidence

During the survey periods, June-September, 1956 and 1957, 1807 tankers berthed at Mina-al-Ahmadi, representing at most 108,000 seamen Of those who required or sought medical attention on the pier, 128 were found to be suffering from the effects of heat From these figures an approximate incidence index of 1 in 850 may be derived, but this is possibly not a true picture of the overall incidence of heat illness on ships in the Persian Gulf, we have no accurate information of the numbers seen and treated at other oil ports on the Gulf—e g, at Abadan, Umm Said, or Dhahran

TABLE I—CLASSIFICATION OF 128 CASES

Syndrome	No of cases
Heatstroke	2
Heat hyperpyrexia	1
Borderline heat hyperpyrexia	5
Heat exhaustion syndromes	
(1) severe	
Salt deficiency, with or without *heat cramps*	59
Anhidrotic heat exhaustion	1
Primary water deficiency	0
(2) mild	
Exercise-induced heat collapse, heat syncope, mild water deficiency, acute heat neurasthenia	60

Classification

Local physicians divide heat illness into three groups—mild heat exhaustion, severe heat exhaustion, and heat hyperpyrexia (including heatstroke) Abundant clinical experience of heat effects, coupled with heavy outpatient sessions, makes further categorisation by laboratory investigation largely unnecessary and impracticable In table I this simple division is correlated as far as possible with classification of the 128 cases according to the most recent proposals of the *Medical* Research Council's Climatic Physiology Subcommittee for nomenclature and coding of heat-illness (Weiner and Horne 1958)

Severe primary water-deficiency heat exhaustion, such as may occur in men lost in the desert, was not seen among the tanker personnel Prickly heat and other skin disease referable to high environmental temperatures are not included in this table

Clinical Observations

Complete absence of sweating and a rise in body temperature above an arbitrary level of 106°F (41°C) constitute *heat hyperpyrexia*—in the presence of environmental heat stress and the absence of any other cause of the pyrexia If in addition the patient has coma, convulsion, or delirium, the condition is by common consent described as *heatstroke* Choice of the arbitrary figure 106°F is unsatisfactory, and heatstroke with a body temperature of 105°F (40 5°C) is described in two cases by Leithead and Wilkinson (1958)

Of the 3 patients listed here, 1 was conscious but irrational with a body temperature of 106°F (41°C) and the other 2—British youths aged 22 and 24—had shown coma and convulsions with temperatures noted by intelligent lay observers to be 110°F (43 3°C) and 108°F (42 2°C) respectively The issue in these two cases had been decided on board ship, before they reached medical attention one recovered (without any apparent residual damage to the central nervous system) after being promptly put in the meat-storage space (the only " cool " compartment of this particular ship), and the other aspirated vomitus and died during correct treatment by applications of chilled water to the body and vigorous fanning to provide air movement

Theoretically, it is inadvisable to apply ice chips or ice-cold water in these cases, because one may induce vasoconstriction which will prevent the blood from circulating through the cooled skin But the successful use of a refrigerator by a resourceful ship's captain illustrates the fact that in practice advantage should be taken of any available cooling device

In 5 patients the body temperature lay between 103° nd 106°F (39 5–41°C) All were conscious and rational, nd have been listed here as cases of *borderline heat perpyrexia*, a term used by Ladell et al (1944) Of adell's 12 patients, 10 had anhidrosis when examined, hereas all our 5 were sweating Urinary chloride excre-on (Volhard technique) ranged from 3 to 11 g per litre, nd, in the 3 cases in which they were estimated, whole-lood and plasma levels of sodium, potassium, and hloride were within normal limits

Anhidrotic heat exhaustion (thermogenic anhidrosis, opical anhidrotic asthenia, heat exhaustion type II) as escribed by Wolkin et al (1944), Allen and O'Brien 1944), and Ladell et al (1944) was encountered only nce. Horne and Mole (1950) and O'Brien (1948) have hown that four to seven months' exposure to a hot cli-nate is usual before onset of this syndrome, and when ney arrived at Mina-al-Ahmadi European tanker crews ad seldom been exposed to heat stress for more than n to fourteen days

The patient listed here was an Indian, aged 36, who had ravelled by passenger ship from Bombay to join an oil-anker in the Persian Gulf He was found to have extensive rickly heat with large areas of miliaria profunda and anhi-rosis on the trunk, his temperature was 102 F (39°C), he had achycardia and hyperpnœa, and he was sweating only on the ace, hands, feet, and perineum His urine contained 3 g odium chloride per litre

Shortly after Sargent and Slutsky (1957), from a com-rehensive review of the eccrine miliarias, concluded that natives of India are free from this syndrome, Jelliffe 1958) described it in Bengali children

Our 59 cases of *salt-deficiency heat exhaustion* have been lescribed in detail elsewhere (Leithead et al 1958) They were distinguished from other exhaustion syn-lromes by the absence (or near absence) of urinary odium chloride, with reduction of blood-chloride in cases thus investigated Muscle cramps (heat cramps, miners' cramps stokers' cramps) were noted in 60% of these patients, not in any of the other groups No clini-cal purpose is served, we think, by separate classification of cramps, which are now believed to be directly caused by salt deficiency

Unless there are muscle cramps, or the chloride levels of blood and urine are known, salt-deficiency heat exhaustion is not readily distinguishable from such conditions as exercise-induced heat collapse or acute heat neurasthenia Generally, however, it is a more severe illness, culminating eventually in oligæmic shock, and most patients need several days' salt and water replacement and rest 3 typical cases in this series required an average of 40 g of salt by mouth before clinical improvement and the reappearance of urinary chloride in significant quantities (i e , above 1 g NaCl per litre)

Heat collapse (Dreosti 1937 and Weiner 1938) and *heat syncope* are allied circulatory disorders Weiner observed syncope in Bantu miners who remained erect after exercise in a hot humid environment (wet-bulb temperature 94–95 F, or 35 C) In unacclimatised immigrants, during their first few days in a hot climate, sudden postural change may cause giddiness and even syncope These disorders are attributed to extensive vasodilatation by direct action of heat, consequent " pooling " of the blood in the lower half of the body, postural hypotension, and hence inadequacy in the supply of blood to the brain. Giddiness, exhaustion, and headache are vague symptoms referable also to mild water deficiency, to acute heat neurasthenia, and to early salt depletion, and unfortunately they parallel the type of complaints chosen by malingerers As operators of tanker fleets naturally aim at a quick turnround of their ships in port, close investigation and differentiation of patients with such mild symptoms was impossible Our practice was therefore limited to separating the severe from the mild cases, but we can say that, though salt deficiency was found in a few patients with mild symptoms, it was invariably present in all severe exhaustion cases Caplan (1943) also found low plasma-chlorides more frequently in clinically severe heat exhaustion

Prickly heat was noted in 25% of all cases, and—except in the single case of anhidrotic heat exhaustion—it bore no apparent relation to the type of heat illness No attempt was made to estimate its incidence in tanker personnel, but analyses by Smith (1957) of sickness returns for Naval vessels in the Persian Gulf in 1948–52 showed an incidence of skin disease (unqualified, but including prickly heat) of about 4%

Ætiological Factors

Environmental Temperatures

To within 7–10 miles of the coast, Kuwait has a desert climate, but beside the sea the air is more humid, and readings taken at the shore end of the pier at Mina-al-Ahmadi reflect the climate experienced in the Red Sea and Persian Gulf These readings are charted in fig 2, along with saturation deficiencies and monthly incidence of marine heat illness for the survey periods It is evident that, at high ambient temperatures, a sustained drop in saturation deficiency is associated with an increase in the amount of heat illness among tanker crews This is mainly due to decreased evaporation of sweat and therefore decreased loss of heat in people whose acclimatisation is insufficient to take the extra heat load Ashore in Kuwait the local physicians recognise that humid spells are liable

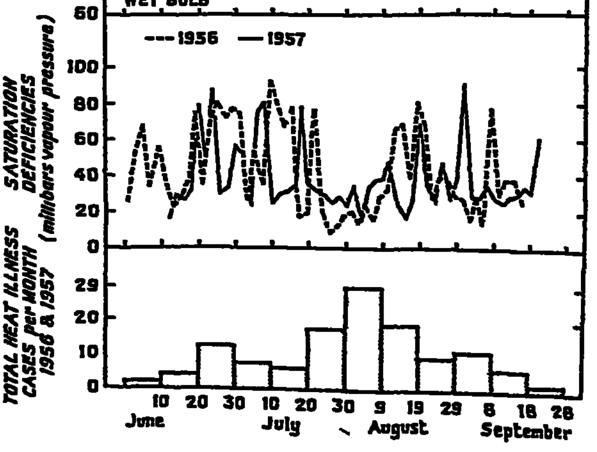

Fig 2—Incidence of heat illness in relation to shade temperature (3 p.m) and humidity readings during summer in Kuwait coastal area. Interrupted lines, 1956 Continuous lines, 1957

to cause heat syncope and collapse among previously healthy immigrant (non-European) workers

Geographical

Heat casualties arise whenever environmental heat stress exceeds the level which is critical for the person concerned They may therefore be encountered far from the tropics—e g, in boiler rooms or coalmines Cases of heatstroke in Britain recently reported by Harris and Hutton (1956) and Stoddart (1958) occurred in an operating-theatre and a Turkish bath

But, although the geographical distribution is wide (Shattuck and Hilferty 1936), we may note that heat illness has always been a feature of Arabia and the Middle East (Friend 1932) By virtue of their poor acclimatisation, arduous duties, heavy equipment, and often unsuitable clothing, Western armies have suffered considerably in Middle Eastern areas "The heat, and the fever" killed members of the Crusade of Edward I (Lindsay 1936) Among British Expeditionary Forces in Mesopotamia during the first world War, there were in one month no fewer than 425 deaths from heatstroke (Willcox 1920), but this harrowing experience of Willcox, and of Hearne (1919, 1932), resulted, through their wisdom, in improved diagnosis, treatment, and prevention, and so in an immediate reduction of mortality The second world war again found unacclimatised troops suffering heat casualties in Iraq (Ladell 1944, Lipscomb 1944, Morton 1944, Croom 1944, Shepherd 1945) Between the wars Marsh (1930) gave a scholarly account of the ætiology and prevention of heatstroke among employees of the Anglo-Persian Oil Company, and Whittingham (1930) reported 26 severe cases among Royal Air Force personnel in Iraq

Shipboard Occupation

As table II shows, occupation played a decisive part in the incidence of heat illness on board ship, which is about three times as common in the engine-room, and twice as common in the galley, as it is on deck The 3 patients with heat hyperpyrexia and the 5 with borderline hyperpyrexia were all working in the engine-room Figures in the middle column are derived by an assumption that the average tanker carries deck and engine-room crews and commissariat in proportion 3 2 1

It is obvious that the occupational hazard is caused by the additional heat given out by engines, boilers, and ovens Of 121 patients for whom records of shipboard occupation were obtained, 57% worked in the engine-room Thomson (1946) found engine-room personnel providing 88% of heat illness on H M S *Queen Elizabeth* in the Indian Ocean Crowden (1954) observed the same occupational influence in a Naval ship in the Persian Gulf

Acclimatisation

Though the word "acclimatisation" has enjoyed the dignity of several shades of meaning—e g, the process of settling-down in a new environment, or perhaps the development of equanimity and temperance in face of the hazards and temptations of the Colonies, it is now falling victim to the harsh objectivity of the times and is used synonymously with the phrase "physiological acclimatisation to heat"

Adaptive physiological changes following exposure to unaccustomed heat have been studied extensively in the past twenty years or so (see Bass and Henschel 1956 and *Lancet* 1956) Present-day views may be summarised as follows Exposure to heat causes vasodilation in skin and muscles, without immediate corresponding increase in blood-volume, and this results in cardiovascular instability, with pooling of blood in dilated vessels, and giddiness or syncope on exercise or sudden postural change At this stage, the man is unfit for physical work in the hot environment Adaptive changes include (1) retention of fluid, with an increase in blood-volume which restores cardiovascular stability, (2) a more rapid onset of sweating in response to a rise in body temperature, and (3) an actual increase in the rate of sweating As a result of such changes, exercise in heat does not raise the heart-rate and body temperature so much as it did previously —i e, ability to work in the new environment improves

TABLE II—OCCUPATION OF PATIENTS ON BOARD SHIP

Occupation	All cases	Total at risk	Index
Engine-room	69	36,000	1 500
Deck	33	54,000	1 1600
Commissariat	19	18,000	1 900
Unrecorded	7	—	—

Agreement over the mechanisms of these changes has not yet been reached But the salt retention and reduction in the chloride content of sweat which is seen in people on a low salt intake during the acclimatisation period (Conn 1949, Robinson et al 1950, Weiner and van Heyningen 1952), and the fluid retention which must precede the rise in blood-volume, suggest that the adrenal gland is involved There is already some evidence that urinary excretion of aldosterone rises during acclimatisation (Hellman et al 1956)

Whatever the mechanism, the process is rapid and may be complete within a week There may also be a long-term acclimatisation, developing over months or even years of residence in a hot climate, but to oil-tanker personnel visiting the Persian Gulf only the rapid changes are relevant Sailing from Europe to Kuwait via Suez, they encounter high temperatures particularly after entering the Red Sea After leaving the Suez Canal the modern tanker reaches Kuwait in ten or eleven days By the time they arrived at Mina-al-Ahmadi, our patients had been ill on average for three to five days—i e, their health had broken down within the usual acclimatisation period

Although a few of the 128 were seasoned veterans of the Persian Gulf, 38 (30%) were making their first *summer* trip to it As oil-tankers never tarry, either at loading or discharging ports, their crews continually pass from cool to hot climates and back This may have a bearing on their state of acclimatisation, for Bean and Eichna (1943) found that in young fit men the acclimatisation conferred by one to three weeks' exposure to heat was retained fully for only two weeks Tankers plying directly between Britain and Kuwait spend three continuous weeks in the heat but are then a further three weeks in a cool environment before being once more outward bound from Suez Therefore on each trip to Kuwait their crew may be regarded as unacclimatised, or at least not fully acclimatised, to environmental temperatures east of Suez

Diet, Fluids, and Salt

Critchley (1947) noted that sailors of H M Fleet preferred hot roast joints, potatoes, and suet puddings even in the Persian Gulf in summer-time So do sailors in British oil-tankers today, and their preference cannot be unreservedly condemned Ingestion of large carbohydrate or fatty meals increases the endogenous heat load, and if the meals are followed by work or exercise in high ambient temperatures, this increase may tip the scales in favour of heatstroke. But diet by direction rather than choice can hardly be recommended for sailors already exposed to monotony.

Nowadays, the average tanker has water-cooling devices which supply chilled and palatable water in adequate quantities, and severe water-deficiency is not seen in the crews. Beer is not regularly available to British tanker crews while at sea, but Italian and French sailors are not denied their customary table wine. Heat illness occurred in a relatively high proportion of Italian ships, and of the 6 cases of borderline heat hyperpyrexia 3 were Italian. The association of heat hyperpyrexia with drinking too much alcohol is well known, but it is by no means invariable, and both our patients with heatstroke were British youths who had taken no alcohol at all before their collapse.

Body salt is derived from what is present in food or added to it. A diet containing meat offers approximately 10–15 g. of sodium chloride daily and in cool climates this is greatly in excess of human requirements. The salt habit has been criticised by Ladell (1957) as a luxury and addiction, and Dahl (1958) has suggested that long-confirmed dietary excess of salt may cause "essential" hypertension. Various ethnic groups have been cited as taking no harm from diets yielding less than 5 g. daily—e.g., Lapps, Eskimos, Indonesian peasants, South African bushmen, and North American Indians. Conn and Johnson (1944) showed that *fully acclimatised* Americans could perform hard work in a hot environment yet remain in salt balance on a total salt intake of 5 g. per day.

The sweat of unacclimatised man contains 2–5 g. of sodium chloride per litre. Conn (1949) puts the average as about 4 g. per litre. Hypothetical application of the predicted four-hour sweat rate (P4SR) scale of McArdle el al. (1947) for young, fit, acclimatised men undertaking moderate work in overalls, to dry-bulb and wet-bulb temperatures and air-speeds recorded by one of us (C. S. L.) in the engine-room of a tanker in the Red Sea and Persian Gulf in May, 1956, suggests a loss of up to 6 litres, or more, during a four-hour watch. As the engineers under observation could not have been fully acclimatised, and the actual sweat rates were therefore probably lower than calculated, salt losses may be put at 12–16 g., or more, in the four hours. The experiments of Conn and of others show that in acclimatised men on a low intake of salt the salt content of the sweat may drop to less than 0.5 g. per litre, thereby "saving the day," but the high incidence of salt deficiency (46%) among our 128 patients suggests that dietary salt intake was inadequate for the circumstances and that in some individuals reduction of the salt content of the sweat had not developed in time to avert onset of the deficiency state.

Sex and Age

Among 302 cases of heat illness among civilians during heat-waves in Chicago, Cincinnati, and St. Louis, males outnumbered females by 238 to 64 (Gauss and Meyer 1917, Ferris et al. 1938, Austin and Berry 1956). But the sex incidence is of no significance to Persian Gulf shipping, for only a few of the gentler sex sail in tankers—as laundresses or stewardesses. At Mina-al-Ahmadi 4 complained of giddiness, headache, and fatigue, but none were febrile or salt-deficient.

The 128 patients ranged in age from 15–65 years but 70% were between 18 and 40. This merely reflects the age pattern of the sailors at risk. Service personnel and other young men working hard in a hot environment suffer heat illness despite their youth: thus of 733 cases reported from such communities, 90% were below 40 years of age (Wallace 1943, Caplan 1943, Borden et al. 1945, Malamud et al. 1946), whereas when the wide age-range civilian populations of Chicago, Cincinnati, and St. Louis (vide supra) were exposed to heat stress 80% of casualties were above the age of 40. The inference seems to be that increasing age, with the onset of degenerative diseases such as arteriosclerosis, coupled possibly with an increase of the body-mass/surface-area ratio (which to some extent influences efficiency of heat loss), increases susceptibility to heat illness.

Nationality

The racial distribution of the patients—again corresponding to that of the sailors at risk—was British 35, Italian 19, Norwegian 16, German 14, Greek 14, French 11, Dutch 7, Indian 5, Chinese 3, Swedish 2, Spanish 1, and American 1.

Over the survey periods, the national flags which contributed the greater bulk of the shipping were British (391 tankers), Norway (363), Liberia (348), France (124), Panama (115), and Italy (100). Since tankers flying the so-called flags of convenience (e.g., Liberia, Panama) carried mixed crews including Italians and Greeks, an index for nationality incidence is not calculable from these figures. However, the proportion of ships of each flag which provided cases of heat illness may cast some light on the influence of shipboard factors: Italian 9%, Panamanian 8%, Liberian 7.5%, British 7%, Norwegian 6%, and French 4%.

The fact that unacclimatised Caucasians fall victims to heat illness more often than people who live in hot climates has somewhat clouded Western medical teaching on the subject. For example, a current British textbook of medicine says that prickly heat is peculiar to white races, whereas in fact Indians and Arabs are by no means exempt. The truth is that, whereas acclimatisation is important, nationality, per se, is not.

General Health

Syphilis, virus pneumonia, enteritis, appendicitis, and malaria complicated 7 of the 128 cases. In a hot environment, infection and gastrointestinal upsets carry an extra risk because fever, anorexia (with reduced water and salt intake), or vomiting and diarrhœa (with increased loss of water and salt) predispose to heat illness.

Prevention

Pickering (1958) quotes Bertrand Russell to the effect that whereas in older civilisations man adapted himself to his environment, the modern American adapts the environment to suit himself. In the desert hinterland of Kuwait, nomadic Bedouins wear long robes to protect themselves from the fierce heat, and during the hottest part of the day they rest in meditative immobility in the shade of their tents. Beside them, the Western oil-company staff wear light clothes, and display health and vigour in contempt of the same heat—but are able to return periodically to bungalows which are supplied with fans, air-conditioning systems, and refrigerators.

In tankers in the Persian Gulf, prevention of heat illness depends on a compromise between these two concepts. In many such ships, sickbays and messing saloons have been provided with individual air-cooling units, and some of the newer tankers have cabin air-conditioning. Ideally, temperatures in resting quarters should be within the range of human *comfort*, and in working spaces within the levels of human *tolerance* to heat In the summer heat of Kuwait, Europeans feel comfortable and sleep well in rooms cooled to about 78°F (25°C) dry-bulb temperature, and this agrees with figures published for Europeans in similar climates, but it is harder to be dogmatic about upper tolerable limits of environmental warmth for men who are working—except in terms impracticably low for ships' engine-rooms in tropical waters

Information on heat tolerance has been reviewed by Bedford and Tredre (1955), and in relation to prevention of heat incapacitation by Ellis (1955) Several physiological indices of heat stress have been evolved but are too complex to be useful to officers of the mercantile marine

The *American effective temperature scale* (E T), which takes into account the temperature, moisture content, and movement of environmental air, was modified by Bedford (1946) to allow for radiant heat in engine-rooms and boiler-rooms, and has been in wide use in the Services—U S and British Weiner and Lind (1955) suggested that acclimatised men are capable of hard work at E T 90–91°F, but for unacclimatised men the maximum figures quoted have not exceeded E T 86°F

Wet-bulb (W B) readings are also of value Haldane (1905) suggested an upper endurable limit of W B 88°F (31°C) for men working in air movement of 150 feet per min Caplan (1943) encountered heat casualties in the Kolar goldfield whenever the wet-bulb temperature rose above 90°F (32°C), and Eichna et al (1945) observed that work became impossible for young fit and acclimatised men in saturated air at W B 96°F (35°C)

Dry-bulb (D B) readings unaccompanied by knowledge of humidity are less useful in assessing tolerance Even in very dry heat the degree of air movement and the duration of exposure, age, acclimatisation, clothing, and activity of the person exposed are all factors of considerable influence Thus Shickele (1947) found that " heat death " conditions certainly prevail when maximum daily temperatures exceed D B 113°F (45°C), while Blagden (1775) and his colleagues exposed themselves to a room temperature of dry-bulb 260°F (127°C) for eight minutes without ill effect

In summary, heat casualties among young working men who may not be fully acclimatised can be predicted at wet-bulb readings above 90°F (32°C) at sustained dry-bulb readings above about 110°F (43°C) and at above 86°F on the effective temperature scale But there seems to be little advantage in recommending that working spaces in ships in tropical waters be kept below these temperatures if in practice this is unlikely to be possible During the late war it was recommended that in British warships in the tropics the effective temperature should not exceed 86°F, but in August, 1951, effective temperatures in the engine-room of one such vessel in the Persian Gulf were between 90 and 95°F (Crowden 1954), and in May, 1956, in the engine-room of a tanker in the Red Sea and Persian Gulf they varied between 85 and 93°F —with no scarcity of old hands to aver that this was mere child's play and that the " real " heat would begin in July

In such circumstances, heat illness can be prevented only if tanker personnel make concessions to the environment, and if they are to do this they must be told what is necessary, and why it is necessary Minard et al (1957) have shown how the incidence of heat casualties among Service recruits was reduced by limiting certain activities during periods of excessive heat

Captains, chief engineers, and other responsible officers should be aware, for example, of the vague premonitory symptoms of heat distress, and should know that if the environmental heat is barely tolerable to a man standing a four-hour watch, such a man is certainly incapable of performing hard work in the same environment for th period *Completely unacclimatised* apprentices, assistan engineers, and other " first-trippers " should not be allowed to judge their own capabilities, for some are too brave Both the *heatstroke* patients reported here w making their fist trip to the Persian Gulf, and one, w was fortunate to survive, developed hyperpyrexia a coma after working for about an hour on electr repairs in a space above the boilers where the tempe ture (recorded *after* the event) was D B 180°F (82 C)

Considerably more attention to salt intake is a required This is reiteration of advice which has of been given without the desired effect, for Thomson (19 found primary salt-deficiency accounting for 89% heat-illness cases on a troopship, Marriott (1950) regard salt-deficiency in tropical countries as " *perhaps the co* monest of all deficiency states ", and Crowden (19 advised an intake of about 30 g of salt daily for engi room personnel at sea in the Persian Gulf in summ months This figure seems to us rational, and implies t addition, at table, to daily food of three unheaped te spoonfuls of salt (or eighteen enteric-coated salt table each containing 0 65 g)

Finally, in the Red Sea and Persian Gulf people suff ing from anorexia and nausea should not be encourag to cease intake of food, water, and salt, as seems to usual And drugs carried by ships in these waters f treatment of gastrointestinal upsets should not conta atropine, which inhibits sweating

Summary

A vast international fleet of oil-tankers now sails in t Persian Gulf, and heat illness aboard the ships is a serio problem, 128 such cases seen at one port *in the summ* of 1956 and 1957 are reported, among which were 3 cas of heat hyperpyrexia (1 fatal), 5 of borderline he hyperpyrexia, 59 of salt-deficiency heat exhaustion, 1 anhidrotic heat exhaustion, and 60 of minor heat syn dromes (unclassified) A large proportion of these cas occurred in the month of August each year

Tanker crews going to the Persian Gulf are exposed t heat especially in the ten days after they *leave* the Sue Canal During this period they have to become rapidl acclimatised, or regain the acclimatisation lost *after the* previous voyage The additional heat-stress of engine rooms and galleys accounted for over half the cases

If heat illness is to be prevented aboard *such* vessels responsible officers must have fuller understanding of th risks Crews must be induced to take supplementar salt in quantities sufficient to replace what they lose i sweat, and officers must be readier to limit activity befor it becomes dangerous For saving lives and *safeguardin* health these personal preventive measures are almost a necessary as maximum air-conditioning of the ships

We wish to express gratitude to our many colleagues in Kuwait to Dr Eric Parry, F R C S , chief of Kuwait State Medical Service, fo permission to investigate patients of the *State* clinic on Mina a Ahmadi pier, and to Mr C A P Southwell, C B E , M C , managin director of the Kuwait Oil Company

Von Willebrand's syndrome is a familial hæmorrhagic disease that has some clinical features resembling true hæmophilia but differs significantly in other ways Thus disproportionate bleeding from minor injuries appears in childhood and removal of teeth or tonsils can cause serious bleeding But in von Willebrand's syndrome males and females are equally affected, the blood-clotting time is normal, but the bleeding-time is prolonged For these reasons the syndrome has been called " pseudohæmophilia " or " vascular hæmophilia "

It is not very uncommon, Buchanan and Leavell (1956) traced 186 published cases and added 13 of their own While investigating their own patients with contemporary techniques they found that the prothrombin-consumption test was abnormal in 5 of 6 tested Later, Singer and Ramot (1956) applied the thromboplastin-generation test to the blood of a patient with pseudohæmophilia and showed that there was a deficiency of antihæmophilic globulin, thus confirming the report of Alexander and Goldstein (1953) Reports of antihæmophilic globulin deficiency in von Willebrand's syndrome have since been published by Matter et al (1956), Nilsson et al (1957), and Fessey and Meynell (1957) among others Biggs and Macfarlane (1958) estimated the antihæmophilic globulin deficiency in 15 members of eleven families with the disease, and in 11 of them the antihæmophilic globulin level was reduced to levels between 1 6% and 45%

Nour-Eldin and Wilkinson (1958a) have described a blood-clotting inhibitor in the plasma of all patients with true hæmophilia or Christmas disease and called it the Bridge anticoagulant after the first patient Since this factor seems to be part of the inherited abnormality of the hæmophilia syndrome, its presence could be used to see if von Willebrand's disease was a member of the hæmophilia group or not For this purpose three patients with typical von Willebrand's disease were studied

Case-reports

Since the three cases have not previously been published, brief clinical notes are given here

Case 1 —A girl, aged 7 years, was referred for investigation with a history of excessive hæmorrhage after trauma No other members of the family were known to be affected, and blood from her parents and a brother, aged 14, was normal At the age of $2\frac{1}{2}$ years she " cut her tonsil on a sweet ", there was profuse bleeding, her hæmoglobin fell to 20%, and she had to be transfused Since then she had had to be transfused on eleven occasions for bleeding after tooth extractions or epistaxes following trauma or infection Large bruises appeared after quite small bumps, but none of the hæmorrhages seems to have been spontaneous The results of blood tests (tables I

TABLE I—BLOOD-CLOTTING TESTS ON PATIENTS WITH VON WILLEBRAND'S SYNDROME

Test	Normal range	Case 1	Case 2	Case 3
Blood-clotting time (min)	4–7	5	5	7

and II) show the typical combination of prolonged bleeding-time and normal clotting-time with normal platelet-count, the thromboplastin-generation test gave results showing a deficiency of antihæmophilic globulin The patient was admitted to hospital for removal of two teeth, and three transfusions in nine days were needed to control the bleeding She has had three further admissions for control of bleeding from her nose, her tonsillar bed, and her gums

Case 2—A boy, aged 8 years, had had frequent epistaxes for five years, sufficiently severe to need blood-transfusion on one occasion He bruised excessively after minor trauma His joints were not affected His father bled unduly after tooth extractions, other members of the family were unaffected, his mother's blood was normal The results of laboratory tests with this patient's blood (tables I and II) show the same combination as in case 1, but the deficiency of antihæmophilic globulin was less severe

Case 3—This boy, aged 11 years, was referred from the Dental Hospital with a history of excessive bleeding after tooth extractions At the age of 5 years removal of a milk tooth had caused severe hæmorrhage, and a blood-transfusion had to be given When he was 7 years old he had two weeks in hospital after tooth extraction, but the bleeding was controlled without transfusion He also bruised excessively after minor trauma No other members of the family were significantly affected, and no clotting anomaly was found in his mother's blood Laboratory tests with his blood gave results very similar to those of the two other patients

Methods

Blood-clotting tests—These were made essentially as described by Biggs and Macfarlane (1957), imidazole buffer pH 7 3 was added to the incubation mixture in the thromboplastin-generation test

Bridge anticoagulant—To determine whether or not this blood-clotting inhibitor was present in the plasma, the method described by Nour-Eldin and Wilkinson (1958a) was used In this method undiluted aluminium-hydroxide-treated plasma is used in the incubation mixture, and the activity of plasma thromboplastin formed is tested on normal as well as patient's citrate-plasma substrate

Results

Table I shows that the three patients had blood-clotting times, one-stage prothrombin-times, prothrombin-consumption indices, and clot retractions within the normal ranges, but they had prolonged bleeding-times Hess test (capillary fragility) at a pressure of 80 mm Hg for five minutes gave positive results in all instances The nail-bed capillaries, however, showed no abnormality when seen magnified 20 times by Zeiss binocular Paper electrophoresis, using barbitone buffer pH 8 6, showed normal bands for the serum-proteins

The results of the thromboplastin-generation tests are shown in table II Antihæmophilic globulin was deficient in the plasma of all the patients, but the serum factors were normal The patients' platelets were fully active when used in this test Table II also shows the effect of mixing each patient's plasma with plasma from another source, the generation of plasma-thromboplastin is much improved on adding plasma from sources other than hæmophilic patients Furthermore, the addition of antihæmophilic globulin separated from pig's plasma (Bidwell 1955) corrected the defect

The results of testing for Bridge anticoagulant are shown in table III In this test the technique of the clotting-thromboplastin-generation test is used, and the clotting-times of the citrate-plasma substrate, using either normal plasma or the patient's plasma, are compared In hæmophilia the clotting-time with patient's-plasma substrate is longer than with normal substrate, and the difference is greater on using undiluted $Al(OH)_3$-treated plasma in the incubation mixture (Nour-Eldin and Wilkinson 1957, 1958a) Table III shows that no such differences were found in any of the three patients, therefore Bridge anticoagulant was absent

TABLE III—TEST FOR BRIDGE ANTICOAGULANT

Case	$Al(OH)_3$-plasma in incubation mixture	Substrate clotting-time (sec)†	
		Normal plasma substrate	Patient's plasma substrate
1	Diluted 1 5	34	34½
	Undiluted*	34½	35
2	Diluted 1 5	15½	17
	Undiluted*	14	14
3	Diluted 1 5	24	24½
	Undiluted*	20	20

* Undiluted $Al(OH)_3$-treated plasma was used in the incubation mixture, 0 05M instead of 0 025M $CaCl_2$ was added, otherwise reagents were the same as in table II

† Same procedure as in table II

Discussion

When a deficiency of antihæmophilic globulin was found in the blood of patients with von Willebrand's syndrome, the link with hæmophilia was apparently strengthened, but our demonstration of the absence of Bridge anticoagulant distinguishes it from both classical hæmophilia and Christmas disease, and fits in with the different type of inheritance and the really different clinical picture In view of this distinction we think that the name "vascular hæmophilia" should not be used "Pseudohæmophilia" seems to be more suitable because it at least indicates that there are resemblances to hæmophilia, notably as regards the deficiency of antihæmophilic globulin Unfortunately pseudohæmophilia is rather a vague title, having been used as a synonym for many blood-clotting defects and vascular abnormalities which bear some clinical resemblance to classical hæmophilia but differ from it in certain laboratory or genetic aspects Another reason for avoiding the use of this title is apparent from the present work, unlike classical hæmophilia, the plasma of these patients is devoid of Bridge anticoagulant Accordingly we prefer to report these cases as "antihæmophilic-globulin deficiency associated with capillary defect" So long as this deficiency is present, it is clear that, for treatment of continued bleeding, fresh blood—i e, blood within two hours of being drawn from the donor—or antihæmophilic factor concentrate should be used, in the absence of the antagonistic Bridge anticoagulant the therapeutic effect should be good

The finding that the platelets were normal in number, morphology, clot retraction, and activity in the generation of plasma-thromboplastin indicates that faulty capillaries are most probably the cause of prolonged bleeding-time With the methods available at present we could not detect the true nature of the defect producing this anomaly in our patients It may be due to a histological abnormality

It is remarkable that no hæmarthrosis or spontaneous visceral bleeding developed in the three patients reported here, in spite of their having a prolonged bleeding-time and increased capillary fragility, thus confirming the observation of Nour-Eldin and Wilkinson (1958b) that these manifestations are related to the concentration of Bridge anticoagulant rather than the level of antihæmophilic globulin

Summary

Three cases of von Willebrand's syndrome, so-called pseudohæmophilia, are briefly described, a deficiency of antihæmophilic globulin was found in their plasma

The Bridge anticoagulant, present in true hæmophilia and in Christmas disease, was absent from the blood of these patients

It is suggested that von-Willebrand's syndrome is a distinct entity and is not a variety of classical hæmophilia, it should be considered as a deficiency of antihæmophilic globulin associated with capillary defect

IT is now well known that many cases of Klinefelter's syndrome are chromatin-positive by Barr's method of nuclear sexing, and it is generally accepted that the finding of chromatin-positive nuclei indicates the presence of the female pair of XX chromosomes (Lennox 1956), hence these apparently very nearly normal males are " genetic " females with sex reversal

There has been much speculation about the mechanism involved (see especially Plunkett and Barr 1956, Segal and Nelson 1957, Witschi et al. 1957, Danon and Sachs 1957, Grumbach et al 1957) It has often been suggested that the defect is genetic (Reifenstein 1947, Sniffen et al 1951, De la Balze et al 1952, Sohval and Soffer 1953, Grumbach et al 1957) Familial transmission through more than one generation has, however, only once been recorded (Reifenstein 1947) and was thought in that family, in which transmission was maternal, to be due to a sex-linked recessive type of inheritance (Reifenstein 1957, cited by Grumbach et al 1957) Affected sibships have more often been recorded (Nadler et al 1950, Sohval and Soffer 1953, Bunge and Bradbury 1956, Grumbach et al 1957) Associated conditions include oligophrenia (Pasqualini et al 1957, Ferguson-Smith 1958) and dystrophia myotonica (Nadler et al 1950, Grumbach et al 1957, Siebenmann 1957) Sibships have been reported with chromatin-positive and chromatin-negative cases (Bunge and Bradbury 1956, Grumbach et al 1957) and with cases of Klinefelter's syndrome and Turner's syndrome (Bassoe, 1956) There is thus some evidence of the presence of a genetic defect, but little of its nature

Attention has been chiefly concentrated in recent papers on the more striking chromatin-positive (genetic female) cases Our own first studies in this field (Ferguson-Smith et al 1957) had as one of their main results the unequivocal demonstration of a histological difference between the testes of chromatin-positive and chromatin-negative patients* but left us, in spite of this, with a clinical impression that the resemblances between the two varieties of the disease are as important as the differences The studies reported here suggest that the defect is genetic and that the mechanisms operating in chromatin-positive and chromatin-negative cases are similar in type They also provide evidence about the nature of the mechanism

The present study is confined almost entirely to accessible patients from the series (now including less than a third of the chromatin-positive cases identified in this area) of 27 cases, 16 chromatin-negative and 11 chromatin-positive, collected by scrutiny of biopsy specimens and re-study of all available patients with azoöspermia and severe oligospermia who had attended a male subfertility clinic in 1955 and 1956 (Ferguson-Smith et al 1957)

Case 9 (table I) and case 24 (table II) did not belong to our original series Case 9 was noticed when he attended a urology clinic with an unrelated complaint He was married and had previously been investigated for subfertility elsewhere Case 24 was unmarried and was referred from an endocrine clinic for testicular biopsy

The fertility-clinic patients are selected in that they are all married men Compared with other series, ours might

therefore be expected to contain more superficially normal men and fewer with subnormal intelligence or with major congenital defect. For example, one of our chromatin-positive cases (see figure) is a tall, powerfully built, deep-voiced "male" who shaves daily. Gynæcomastia is absent. Facial and body hair, although somewhat scanty, is well within normal limits. Measurements are moderately eunuchoid (height 1·87 m, span 1·92 m, from crown to pubis 0·89 m, from pubis to sole 0·98 m), but the main pointer to abnormality revealed by clinical examination is the presence of small firm testes, each about 20 mm long. The great ease with which cases like this can be overlooked is of considerable importance in connection with our estimate of the absolute frequency of Klinefelter's syndrome, and with our suggestion that its familial incidence must be higher than is generally recognised.

Superficially normal 'male' who is chromatin-positive.

Absolute Frequency

A rough estimate of the minimal incidence of Klinefelter's syndrome (of some importance as regards its genetics) can be derived from our figures. Most of the subfertility clinic's patients come from a relatively narrow age-range, the decade of maximal attendance with us being 28–37 years. In this decade we have 4 chromatin-positive and 4 typical chromatin-negative patients with Glasgow addresses. The 1,000,000 inhabitants of Glasgow include 72,000 of either sex of this age. If we have collected all the cases in Glasgow, the frequencies indicated are 1 : 18,000 of each. But not all such persons marry, not all married patients seek advice for their sterility, and not all persons seeking such advice are referred to this clinic. Clearly, even in this decade we cannot have collected all the cases in Glasgow into this one series. We do not think that any random or unrecognised errors in our estimate can counterbalance these factors, and conclude that the true frequency of both chromatin-positive and chromatin-negative varieties of the syndrome can hardly be less than 1 in every 10,000 (reputed) male births.

Family Studies

None of our patients, so far as we know, are related, and it was impossible to examine more than a fraction of the relatives, but important information was obtained by careful questioning of 25 of our patients. These results show one minor discrepancy from their earlier presentation in preliminary form (Stewart et al. 1957), 1 chromatin-negative case having been eliminated because of doubt over the significance of the biopsy finding. (An exact histological definition of chromatin-negative Klinefelter's syndrome has not yet, we believe, been achieved but a more detailed consideration of our present views on this question is to be published elsewhere [Ferguson-Smith et al. 1958].)

Propositi.—Associated inherited defects were inconspicuous. Some of our patients were clearly of low intelligence, but formal intelligence testing was not done.

Sibs.—One of our chromatin-negative patients (case 18) has a brother, also chromatin-negative, who shaves once a week and is grossly eunuchoid (height 1·70 m, span 1·85 m) but has testes of normal size. His only other brother is married and has three children. Since the family are refugees from Central Europe, details of the parental generation are unavailable. None of our other patients has reported any significant deviation of the sex ratio of the sibs (tables I and II). The average age is too low for accurate estimates of childlessness, but many are married and fertile.

Parents' sibs.—Among the aunts and uncles of the propositi are most curious anomalies. Essentially they consist in an excess of childless uncles, paternal in the chromatin-positive cases (table I) and maternal in the chromatin-negative cases (table II). In the latter group there is no excess of uncles, but in the families with chromatin-positive propositi there are an excess of paternal uncles and a deficiency of paternal aunts, shown by disturbance of the sex ratio.

In calculating the proportion of childless to fertile adults we have omitted those who died young (though we have included them in calculating the sex ratio). We have, however, included the unmarried (of marriageable age) in estimating childlessness. Failure to marry seems to be as distinct a characteristic of these families as infertility when married, and, if some of these childless uncles are examples of Klinefelter's syndrome (or something closely allied to it), eunuchoidism and lack of sexual drive may well have been an important factor. Two figures in table I require brief comment.

(1) The 10 who "died young" include 9 members of a single family with the remarkable sex ratio of 18 males to 2 females. 4 were killed in a single accident, and 5 died in the 1914–18 war, so the natural suspicion that the high death-rate is due to congenital defect of some kind is unjustified.

(2) There is a high ratio (6 : 8) of childless to fertile paternal aunts, but this is based on relatively small numbers and is not formally significant, and we have assumed it to be due to chance.

As regards the individual families, the excess of childless uncles is limited to 3 of 9 chromatin-positive and 5 of 15 chromatin-negative cases. The three affected families with chromatin-positive propositi all show an abnormal sex ratio in the parental generation. No abnormal sex ratio can be shown in the propositi's own generation, nor (though this is less important, because many of the sibs are still young) any excess of infertility. The high average size of family in the parental generation in table I has probably helped to make the effect obvious. However, if all the cases were familial, some abnormality of the sex ratio among sibs would have been expected in spite of the smaller families. We must therefore conclude that only some of the cases are familial, the tabulated figures suggest about a third in both varieties of the syndrome, but a much larger series would be necessary to establish this with any exactitude.

Calculation of Significant Differences

Table I.—The proportion of childless to fertile adults for paternal aunts, maternal uncles, and maternal aunts of chromatin-positive propositi are 6 : 8, 6 : 16, and 6 : 17 respectively, but these three groups belong statistically to the same population, and therefore the proportions can be combined (18 : 41). The proportion for paternal uncles (15 : 12) differs from the combined proportion and the difference is significant ($\chi^2=4{\cdot}914$, $p<0{\cdot}05$). The sex ratio of males to females at birth is 106 : 100, therefore the expected ratio for 52 paternal uncles and aunts is 26·8 : 25·2. The discovered sex ratio (37 : 15) differs from this, and the difference is significant ($\chi^2=8{\cdot}081$, $p<0{\cdot}01$).

Table II.—A similar calculation for relations of chromatin-negative propositi shows a proportion for maternal uncles (13 : 12) different from the combined proportion for the others (17 : 55), and the difference is significant ($\chi^2=6{\cdot}898$, $p<0{\cdot}01$).

Twinning

Our earlier histological work suggested analogies (which still hold in some respects) between the sex-reversed gonad of chromatin-positive Klinefelter's syndrome and the partially sex-reversed ovary of the freemartin in cattle (Lillie 1917). We therefore paid special attention to the incidence of twins in the present families. We know of no chromatin-positive patient with Klinefelter's syndrome who has had a normal male twin, so the direct comparison with the freemartin fails at once. Moreover there are three known cases of human dizygotic twins in which blood-group studies have proved the occurrence of intrauterine circulatory mixing, and each consists of a male and a normal (proved fertile in two cases) female (Dunsford et al. 1953, Booth et al. 1957, Nicholas et al. 1957). However, if our cases came from families with a high incidence of twinning, it might have been worth considering the possibility of death in utero of a male twin which had initiated sex-reversal changes, an unlikely but not wholly indefensible hypothesis. However, our data (table III) show no significant excess of twins among the families of the propositi and lend no support to the hypothesis that these patients may be freemartins.

TABLE III—INCIDENCE OF TWINS IN FAMILIES OF PROPOSITI

—	Families of 9 chromatin-positive patients			Families of 15 chromatin-negative patients		
	Total no. of individuals	Pairs of twins	Families with twins	Total no. of individuals	Pairs of twins	Families with twins
Propositi and siblings	32	1	1	65	1	1
Nephews and nieces	33	0	0	80	2	2
Parents, uncles, and aunts	115	4	2	130	0	0
Total	180	5	3	275	3	3

Colour-blindness

Colour-blindness, the commonest readily demonstrable sex-linked recessive character, can be used to distinguish groups of individuals with one X chromosome, in whom it is common, from those with two, in whom it is rare. Polani et al. (1956) applied this reasoning successfully to Turner's syndrome, and Bishop et al. (1956) suggested that the method might be used in Klinefelter's syndrome. We therefore tested colour-vision in most of our patients. Proof of a negative is needed with the chromatin-positive cases, and this will need a very large series, it is hoped, however, that the collected material of Dr Polani, to which our own cases are being added, will soon reach levels of statistical significance. Colour-blindness has, however, so far been found only in our chromatin-negative cases, and it seems already reasonable to predict that the method will again serve to prove that nuclear sexing has been a reliable index of the number of X chromosomes present (Polani et al. 1957).

Discussion

The present series is unusual in several respects. It was collected in a comparatively short time from a two-year sample of patients attending a male subfertility clinic, a highly specialised field which apparently has not hitherto been systematically explored for this purpose. From this sample, unselected in other ways, we calculated that the incidence of both chromatin-positive and chromatin-negative Klinefelter's syndrome is at least 1 of each in every 10,000 male births. The condition is clearly much more common than had previously been supposed. It follows that many patients with Klinefelter's syndrome go through life undiagnosed, and in fact very few of the present series had been labelled "Klinefelter's syndrome" until after the present investigation had started.

Another very important feature of the present series is the relative normality of outward appearance of many of our patients (see figure). We have previously noted (Ferguson Smith et al. 1957) that several of our patients, including 4 chromatin-positive, had spermatozoa in their seminal fluid when first seen, and it is clear that few of the cases conform to, or could be recognised from, the classical descriptions of the syndrome (Klinefelter et al 1942) or its modifications (Heller and Nelson 1945, Howard et al 1950) Yet the concurrence of testicular histology, hormone assays, and nuclear sexing makes it certain that these cases belong to the same group as the more obvious examples

With greater awareness, diagnosis becomes easier, and the two clinicians among us have already begun to recognise the condition in patients referred for totally unrelated complaints The use of buccal smears for nuclear sexing makes diagnosis of the chromatin-positive cases easy and certain, but equally confident diagnosis of chromatin-negative cases requires biopsy, although the condition can be suspected from the clinical appearances and to some extent confirmed by the pattern of excretion of hormones It will therefore be difficult to establish the true incidence of chromatin-negative cases In contradistinction to most previous studies our own suggests that chromatin-negative cases are at least as common as the chromatin-positive variety

Our crucial finding is the excess of childless uncles (tables I and II) A possible attractive explanation is the presence, in the families concerned, of a substantial number of unrecognised cases of Klinefelter's syndrome The existence of individuals who should have occupied the position of paternal aunts to our chromatin-positive patients but have apparently been sex-reversed into sterile " males " would explain both the high incidence of childlessness and the change in the sex ratio In the families of our chromatin-negative patients a corresponding number of affected males on the maternal side would produce a similar incidence of childlessness, but, since the sex is not reversed, the sex ratio would not be affected

There are two difficulties in accepting this

(1) We have not yet proved that any of our childless uncles have Klinefelter's syndrome, but this we believe to be solely due to accidental circumstances which have made it impossible to examine members of the most important families (Hearsay evidence of small testicles has been obtained in 1 case Efforts are being continued, but many of the males concerned are dead or otherwise inaccessible)

(2) Sibships containing several cases of Klinefelter's syndrome should be common, whereas only a few familial cases have been published This seems to be a serious objection to the theory, but may only mean (as emphasised above) that the great majority of cases go completely unrecognised

The somewhat complex genetic implications can only briefly be considered here We have been very much influenced by a strong clinical impression that chromatin-positive and chromatin-negative cases are variants of the same syndrome We therefore accepted the evidence of tables I and II as suggesting not only a genetic mechanism but also similar modes of inheritance, it also provides evidence of the nature of this mechanism

(1) The presence in two generations—presumptive in our cases and established in Reifenstein's (1947)—suggests a dominant character

(2) The seeming transmission by the parent of sex opposite to the presumptive genetic sex of the patient indicates that the condition is sex-controlled (A sex-controlled condition is one in which expression of a defect is limited to one or other sex)

(3) This dominant character seems not to be sex-linked (carried on the unpaired portion of the X chromosome), because some of the chromatin-positive patients with apparently affected paternal uncles had fertile paternal aunts The defect therefore seems to be autosomal (The colour-blindness data, which strengthen the view that chromatin-positive patients were genetic females (XX), is further evidence that the sex chromosomes are normal)

The defect must arise by gene mutation or by chromosomal aberration Possibly more than one mechanism may operate, but only a chromosomal aberration can readily explain the association with other hereditary conditions and the occurrence of chromatin-positive and chromatin-negative cases in a single sibship The most hopeful line of explanation invokes the balance theory of sex inheritance (Goldschmidt 1955), which recognises the presence, both in males and females, of masculinising (M) factors outside the X chromosomes and probably in a pair of autosomes Danon and Sachs (1957) considered that mutation, a qualitative abnormality involving such an M gene, might be causal in chromatin-positive cases, and a more explicit hypothesis of its mode of action in these cases was put forward in an editorial accompanying their paper (*Lancet* 1957)

We prefer to suppose that the defect is quantitative, with duplication of the M locus in one chromosome of chromatin-positive cases and deletion of this same locus in chromatin-negative cases The chromatin-positive patients would be masculinised females due to effective triplication of the M locus, and the chromatin-negative patients would be feminised males, or at least males of subnormal masculinity, due to deletion of one of the normal two M loci Such a defect must clearly be transmitted by a carrier whose sex was opposite to the (genetic) sex of the propositus, thus explaining the opposed maternal and paternal transmissions of the two varieties of the disorder

We do not wish here to do more than to show, on the evidence of our own cases, that a genetic mechanism appears to be common to both chromatin-positive and chromatin-negative varieties of Klinefelter's syndrome, and that chromosomal aberrations resulting respectively in excess and defect of the number of M genes present afford the best explanation yet available Although translocation (Plunkett and Barr 1956) merits careful consideration, the most probable basis seems to be some form of inversion cross-over

More detailed consideration of the nature of the chromosomal aberration(s) involved must await further data It is clear that further work on the families of patients with Klinefelter's syndrome is required Simple statistics of family size such as we have presented could be readily collected in most cases Special efforts should be directed to finding unsuspected examples of the syndrome in families in which there seems to be a high incidence of childless uncles Families with associated congenital traits also deserve especial attention

We recognise that the evidence we have presented for familial transmission of the syndrome is far from perfect, but we believe we are justified in drawing attention to the possibility, because establishment of a mode of transmission of the defect would greatly clarify our ideas of its fundamental nature

Summary

Klinefelter's syndrome is probably a good deal commoner than is generally realised, an incidence at least 1 10,000 each for chromatin-negative and chromatin-positive varieties being suggested

The possibility of familial transmission, at least in some cases, is indicated by the presence of an excess of childless males among the parents' sibs, limited to the father's sibs (indicating paternal transmission) in the chromatin-positive cases and to the mother's sibs (indicating maternal transmission) in the chromatin-negative cases

In addition to the many members of our own departments who have helped us, we have to thank Dr A D T Govan for hormone estimations, Prof L S Penrose for reading our manuscript, Dr R. A Robb for help with the statistics, and Prof E J Wayne for permission to publish one case

ACUTE PHARYNGITIS ASSOCIATED WITH ADENOVIRUS TYPE-3 INFECTION

OF THE CENTRAL PUBLIC HEALTH LABORATORY, COLINDALE, LONDON, N W 9

MOST outbreaks of acute respiratory disease attributed to adenovirus infection have been of pharyngitis associated either with conjunctivitis or with tracheobronchitis and occasionally pneumonia Pharyngoconjunctival fever, as the former syndrome has been called, seemed at first to be due only to type-3 virus (Bell et al 1955, Cockburn et al 1956, Sobel et al 1956), but there is now evidence that types 4, 7, and 14, and perhaps other types, may cause a similar illness (Forssell et al 1956, Kendall et al 1957, van der Veen, personal communication) Most outbreaks of pharyngoconjunctival fever have been in summer, and it has been suggested that swimming-baths may be responsible for spreading infection and perhaps for the conjunctivitis The second syndrome mentioned—acute pharyngitis with frequent involvement of the lower respiratory tract but without conjunctivitis—has been found almost entirely among military recruits in the winter months (Berge et al 1955, Hilleman et al 1955, Andrews and McDonald 1957, van der Veen and Kok 1957) and has been associated with several types of adenovirus, including type 3

The outbreak here described took place in a 'boys' residential public school in Berkshire during February and March, 1957, and was apparently due to type-3 adenovirus Though pharyngitis was the main sign, there was little conjunctivitis and no bronchitis or pneumonia A rather similar epidemic, associated with type-7 virus, in a school in the North of England during the autumn of 1955, was described by Tyrrell et al (1956)

The Epidemic

It is difficult to be certain about the date of the first case, because the epidemic was preceded in January by a small outbreak of a febrile illness often accompanied by severe muscle pains This was thought to be Bornholm disease, but no evidence of Coxsackie virus or of adenovirus infection was found at that time in specimens taken from 10 patients and examined in the laboratory A few cases of pertussis during the same period further complicated the picture However, the accompanying figure shows that there was a major epidemic at the end of February and during March

From Feb 25 until the end of the term the illnesses seemed clinically homogeneous and different from what had gone before During this time 134 (34%) of the 395 boys in the school were admitted to the sanatorium or to a dormitory set aside to take the overflow All the boarding-houses suffered to about the same extent, the only systematic feature apparent in the distribution of cases was that they were more among the young than the old A possible explanation of this was that older boys slept in cubicles and not in dormitories Attack-rates by year of birth were as follows 1938, 8%, 1939, 21%, 1940, 37%, 1941, 31%, 1942, 42%, and 1943, 47% Only 5 adults were affected—3 of 35 masters and 2 of 10 nurses or house-matrons

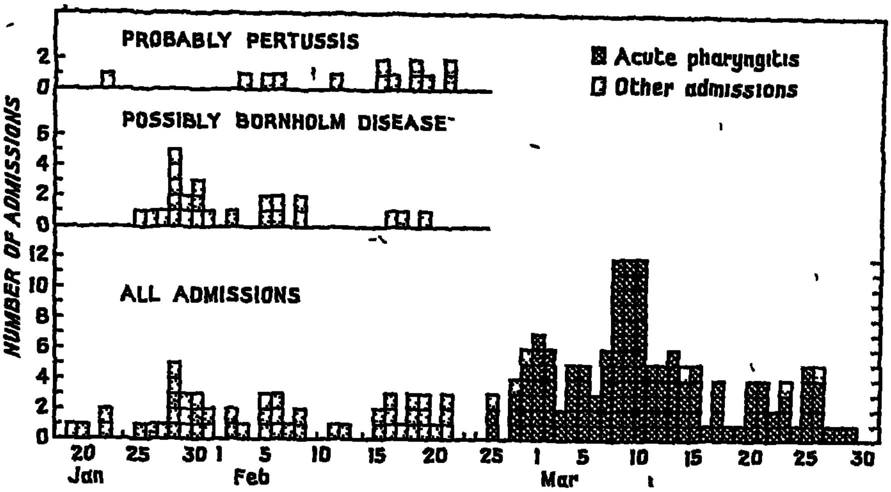
Examination of serial intervals between dates of onset by dormitory gave no indication of the incubation period In 1 boy it must have been at least six days, he left school alone on March 16 to sit an examination in Oxford and became ill on his way back to school on March 22, virus was isolated from a throat swab taken from him on the same day

Clinical Features

The onset of the illness was usually sudden, with pyrexia of 101–103°F falling gradually to normal in four to six days The predominant symptoms were sore throat, headache, and a slight dry cough Nasal symptoms, usually of obstruction, were present in just under half the patients, and sweating was prominent in about a third Other and less common complaints were of hoarseness, pain in or behind the eyes, general muscle pains, and dizziness The fauces were injected, many boys having pin-head vesicles on the soft palate Apart from 2 cases with definite conjunctivitis and 1 with obvious enlargement of the cervical lymph-glands, there was little or no evidence of lymphadenopathy or of conjunctivitis Recovery was usually rapid, the only complications were 2 cases of otitis media, which were treated with penicillin and settled rapidly No symptoms or signs of bronchitis or pneumonia were found Boys who remained febrile for more than four days were treated with penicillin, and this usually coincided with a fall in temperature

Laboratory Methods

Attempts to isolate the virus were made in a similar manner to that described by Kendall et al (1957) HeLa-cell cultures were grown



Daily admissions to school sanatorium

in a medium containing 20% human serum, before inoculation the serum was removed from the cell culture by washing and replaced by a maintenance medium containing 2% rabbit serum 0 2 ml of Hanks' salts solution, into which throat or eye swabs had been broken, were inoculated into each of two tubes of HeLa-cell cultures The cultures were kept for fourteen days and, if negative at the end of this period, were given a blind passage in two more tubes of HeLa-cell culture

When degeneration suspected of being due to an adenovirus occurred, the culture tubes were frozen and thawed, and the fluids were tested by the complement-fixation test for the presence of adenovirus using a known positive serum Viruses found in this way were typed in HeLa-cell cultures containing 0 5 ml of maintenance medium to which was added 0 1 ml of type-specific serum followed by 0 1 ml of suspected virus under test The dose of virus was adjusted to give complete degeneration in two to three days The sera used were those of types 2, 3, 4, and 7, and were supplied by Dr B E Andrews They had been prepared in rabbits which had received a series of intravenous injections of supernatant fluids from HeLa cultures infected with adenovirus prototype strains

The complement-fixation test was performed in the cups of plastic hæmagglutination plates (World Health Organisation 1953) Serum, complement (2¼ M H D), and antigen were mixed in 0 1-ml volumes and incubated at 37°C for one and a half hours, 0 2 ml of a 1% suspension of sensitised sheep red blood-cells was then added After thirty minutes at 37°C the plates were stored overnight at 4°C, and the results were read next morning Titres recorded were the highest serum dilutions showing about 75% or more of the red cells unlysed The antigen was used at the optimal dilution and was prepared from cultures of HeLa cells infected with RI-67 virus (adenovirus type 4) This was supplied by the Standards Laboratory, Colindale

Laboratory Findings

Samples of blood were taken from 11 patients in the acute and convalescent stages Throat swabs for virus-isolation tests were taken from 10 of these and from 4 others 8 of the 11 pairs of sera gave a fourfold or greater rise in adenovirus complement-fixing antibody The 3 negative results were in boys from whom the convalescent-blood specimen was not taken until eight weeks after the onset of illness Complement-fixation tests for influenza A, B, and C, psittacosis, Sendai virus, and *Rickettsia burneti* were all negative and so was the *Streptococcus M G* agglutination test for atypical pneumonia

Adenovirus strains were isolated from 8 of 14 throat swabs tested Serological evidence of adenovirus infection was found in 3 of the failures, the remaining 3 were in boys from whom swabs were not taken till the fifth or sixth day of illness All 8 strains were found to belong to type 3 13 of the 14 throat swabs were tested in fertile hens' eggs for the influenza viruses and found negative

Nose and throat swabs from 42 cases at various stages of the outbreak were examined by Dr N Wood, of the Public Health Laboratory, Reading, who reported a heavy growth of hæmolytic streptococci in 1, a moderate growth in 2, and a scanty growth in 3 1 of the boys with a moderate growth of hæmolytic streptococci developed a scarlatiniform rash, but he also had a fourfold rise in adenovirus complement-fixing antibody

Summary and Conclusion

An epidemic is described of acute pharyngitis in a boys' public school in Berkshire during February and March, 1957

A third of the 395 boys were admitted to the school sanatorium, the attack-rate varying inversely with age

The symptoms and signs were those of acute pharyngitis, only 2 patients had definite conjunctivitis, and none had bronchitis or pneumonia

Laboratory tests on a representative sample of patients indicated that the outbreak was caused by infection with adenovirus type 3

TREATMENT OF INGROWING TOENAILS

ROGER BREARLEY
M B Lpool, F R C S
SENIOR SURGICAL REGISTRAR, WHISTON HOSPITAL, PRESCOT, LANCS

ONLY thirty-nine papers wholly on ingrowing toenail seem to have been published in the past fifteen years, three of them in British periodicals (Nuttall 1942, Zadik 1950, Kemp 1955) This comparative silence is not due to universal agreement on the subject, five textbooks of surgery chosen at *random* offer eleven different methods of treatment Usually these methods are not based on explicit pathology, but, when they are so based, usually the statement is made simply that pressure from tight shoes and socks, combined with cutting the nail short, or trimming away its corners, leads to pressure ulceration at the lateral edge of the nail, followed by suppuration and granulation

A fuller account is given (in an article not exclusively concerned with ingrowing toenail) by Lake (1951), who describes two varieties

(1) *Juvenile type*—Commonest in the age-group 14–18, especially in males The nail is flat from side to side, the lateral fold being large and overhanging At first only discomfort is felt Ulceration, suppuration, and granulation follow later Lake doubts if tight shoes are a cause

(2) *Adult type*—Usually after middle age The transverse curvature of the nail is much increased, with the result that the edge digs into the toe It causes discomfort and callosity but seldom suppurates

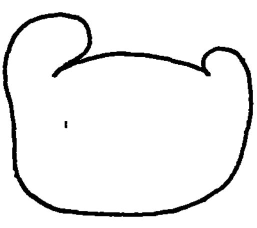

Fig 1—Transverse section of terminal phalanx of hallux with ingrowing toenail of juvenile type

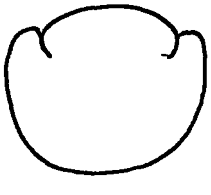

Fig 2—Transverse section of terminal phalanx of hallux with ingrowing toenail of adult type

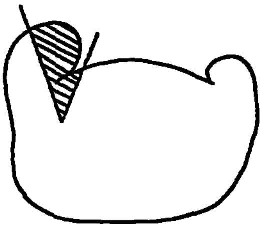

Fig 3—Watson Cheyne's operation shaded area is excised

Pathology

My personal observation confirms Lake's findings Although the age correlation is not invariable, the morphological distinction is real and important, and the terms " juvenile " and " adult " are convenient

In the juvenile type (fig 1) the nail may be normally arched, flat, or even slightly concave The edges are directed outwards, away from the bone Ingrowth may occur at the medial or lateral side or both The toe is often moist, with white macerated skin The affected nail-fold is greatly enlarged, burying the lateral margin of the nail and partly concealing its dorsal aspect. The pulp of the terminal phalanx seems to be abnormally flaccid and yielding, and can be rolled dorsally round the side of the toe, increasing both the width of the phalanx and the depth of the nail-fold To some extent this displacement of the pulp is permanent, but it is momentarily increased with each step as the toe is pressed down From the dorsal aspect the widening of the terminal phalanx is strikingly obvious by comparison with the proximal phalanx (figs 4 and 12) Because of its increased width, the affected phalanx receives an impression on its lateral aspect from the second toe (fig 5), and the sideways and dorsal displacement of the pulp leads to flattening of the plantar surface This throws the weight-bearing point proximally, and a callosity may develop just distal to the interphalangeal skin-crease

Ætiology

Trimming away the corners or lateral borders of the nail is undoubtedly harmful and may precipitate ulceration and sepsis The role of tight shoes is more doubtful. They always offer an easy target for abuse, but it is noteworthy that the affected part is wider than it should be, not narrower, and that females, who are more prone to wear narrow shoes, are less commonly affected than males Lake concurs in disbelieving that shoes are responsible

On the other hand, many of the patients work in gum-boots, or at occupations in which the feet are constantly wet, and some seem to have primary hyperhydrosis The wet macerated skin, which has already been mentioned as a common finding, contributes to the general softening, which allows such ready displacement of the pulp, it also hastens the onset of pressure ulceration at the edge of the nail Laxity of the pulp seems to be the crucial factor,

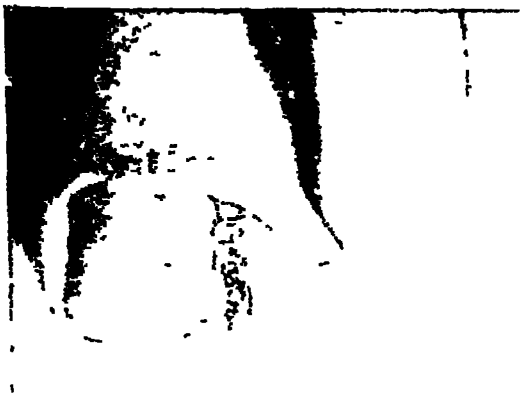

Fig 4—Toe before operation

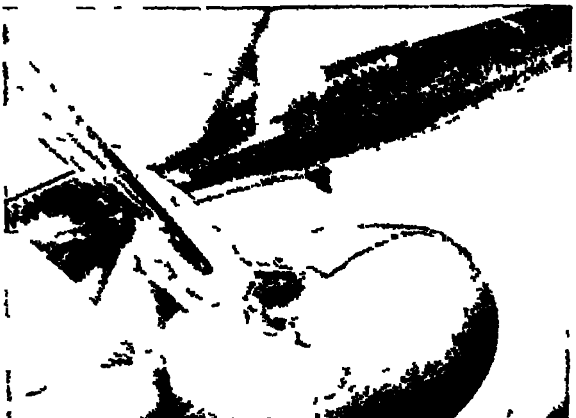

Fig 6—Avulsion of undermined strip

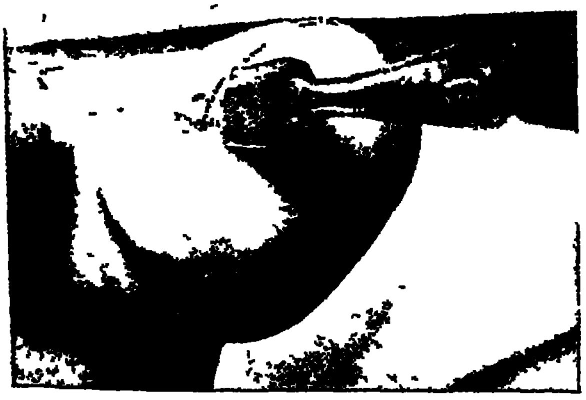

Fig 5—Undermining with blunt dissector

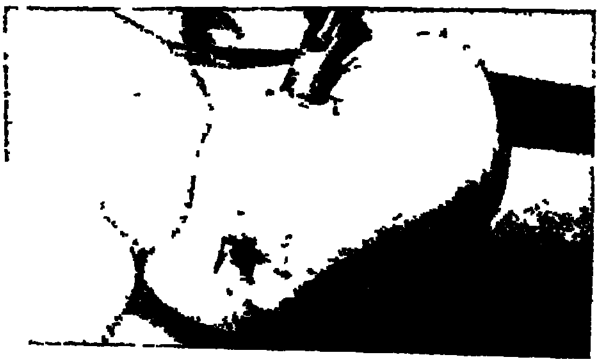

Fig 7—Introduction of scalpel.

however Its cause is not evident, though its effects are clear enough The bony phalanx and nail are firmly bound together as a rigid unit which, when the toe bears weight, the flexors press down into the soft pulp, which streams up round the side of the bone pushing against the edges of the nail and swelling the nail-fold

The adult type (fig 2) is a much less common cause of symptoms The specific feature is a tendency of the edges of the nail to turn in towards the phalanx Softening of the pulp is not found In the absence of diabetes and of arterial occlusion it does not usually cause ulceration

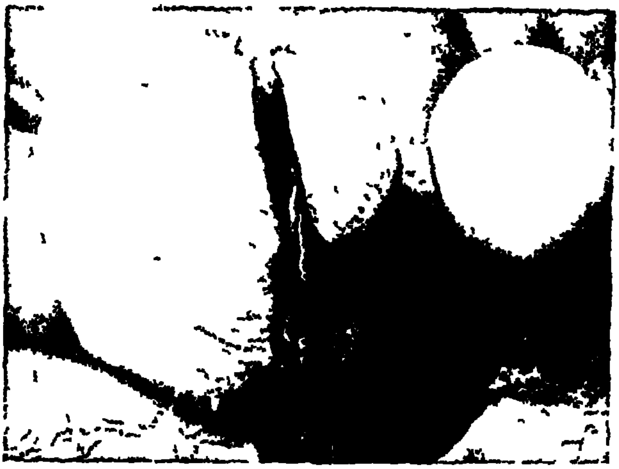

Fig 8—Formation of flap

Treatment

The remedies suggested in standard textbooks include the following

(1) Cutting the nail square, packing cotton-wool beneath the corners, and wearing wide shoes

(2) Thinning the centre of the nail by scraping

(3) Cutting away a V at the centre of the free edge of the nail

(4) Avulsion of the nail with or without curetting away granulations

(5) Filleting the nail-bed off the dorsum of the phalanx

(6) The same, with skin-grafting of the raw area

(7) Zadik's operation (filleting off the proximal portion of the nail-bed, and closure by dorsal skin-flap)

(8) Watson-Cheyne's operation (fig 3)

(9) Willett's operation (see below)

(10) Amputation of half the terminal phalanx, including the nail-bed, and primary closure by plantar flap

(11) Amputation of the terminal phalanx

In the absence of ulceration, suppuration, and granulation conservative measures (1), (2), and (3) usually succeed, especially in lesions of the adult type On the infrequent occasions when infected adult-type lesions (not due to diabetes or to ischæmia) do not yield to conservative methods, amputation of half the phalanx, with ablation of the nail-bed, is satisfactory However, most patients requiring operation have infected juvenile-type lesions

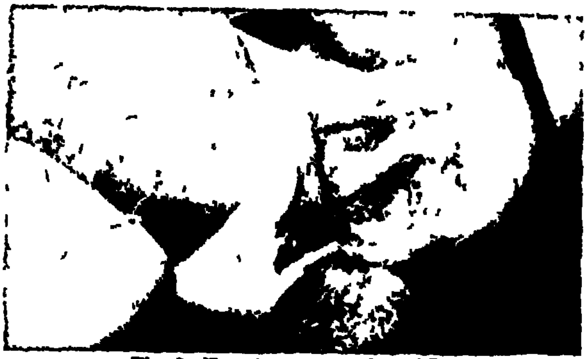

Fig 9—Toe after amputation of flap

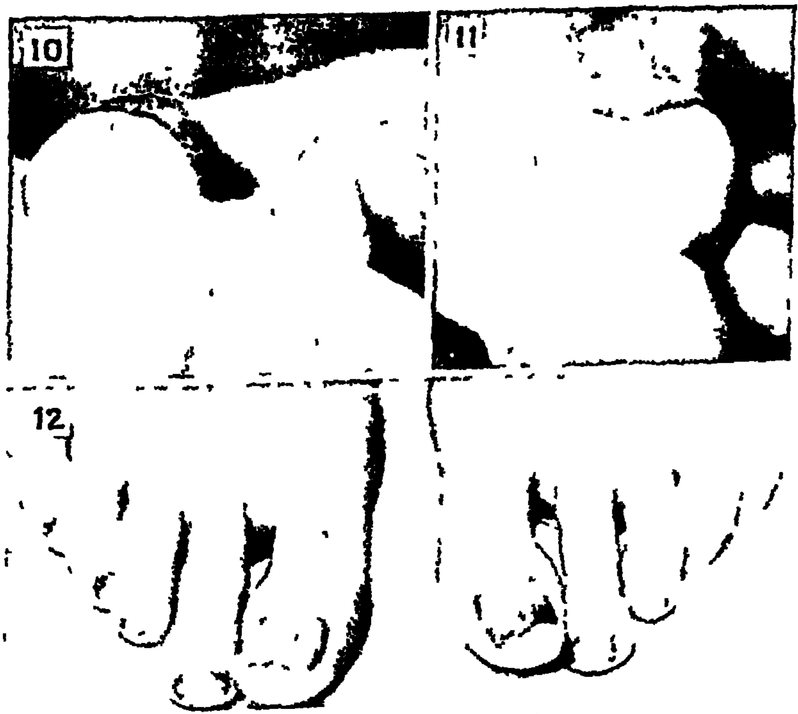
For these the conservative measures (1), (2), and (3) are insufficient Avulsion (4) is followed by recurrence when the nail regenerates, and (5), (6), and (7) are often marred by painful recurrent spicules of nail and produce deformity Watson-Cheyne's operation has both these faults and also leads to recurrences indistinguishable from the original condition The amputations (10) and (11) are mutilating, and occasionally healing is delayed by osteomyelitis or by sinuses

I describe here a new method, similar in principle to Willett's operation, which is suitable for all juvenile-type cases requiring surgery Willett's operation is described as follows (Burrows 1955)

> "This aims at the production of a flat scar along that side of the nail which tends to grow in A tenotome is passed in at the side of the base of the nail, deep to the skin and undercutting it to a width of half an inch The tenotome is then worked forwards to beyond the tip of the nail, thus raising a flap of skin half an inch wide along the whole nail margin, this flap is cut off at its base and the raw area allowed to heal by granulation "

Present Operation (figs 4–9)

The toe is cleansed Digital-nerve block or general anæsthesia is induced A McDonald's blunt dissector is



Figs 10-12—Two years after operation

passed beneath the nail at the affected side, and the strip thus undermined is cut free and avulsed A scalpel is introduced at the proximal end of the groove between nail-fold and nail-bed so as to bisect the angle between the two It is pushed through to emerge from the lateral margin of the toe Its point of emergence should be well down towards the plantar surface, so that the points of entrance and exit are at least half an inch apart. The knife is then advanced distally, cutting a flap consisting of the nail-fold and a substantial strip from the side of the toe (fig 8) The knife is then turned round, the flap is tapered off and amputated at its base, bevelling off the bare area proximally (fig 9) The toe is wrapped tightly in a soft-paraffin gauze bandage, which is left for a fortnight, unless there are signs of gross sepsis The tourniquet shown in the photographs is a great help though not essential

The following points require special emphasis

(1) This operation is unsuitable for the adult type of ingrowing toenail

(2) The knife enters the angle between nail-bed and nail-fold The nail-bed is not cut in any way

(3) It is essential to remove enough soft tissue because the mobile pulp is always ready to roll round the phalanx and create a new nail-fold Any excision less than that illustrated is likely to fail

Results

I have done this operation regularly for the past seven years Properly carried out in appropriate cases, it is always successful It produces no deformity of toe or nail, no discomfort or loss of function, and no recurrence There are no complications such as wound infection, osteomyelitis, and recurrent nail spicules The period of disability is reduced to a minimum because the operation can be done on outpatients on their first visit Suppuration is no contraindication, indeed the operation is a most effective way of terminating sepsis After the bandages have been changed on the fourteenth day, normal walking is possible and the patient can return to sedentary or light work

Figs 10–12 show the result two years after operation The toes are the same ones illustrated in figs 5–9 Although the patient still cuts the corners of the nails rather short, there is now no tendency to ingrowth, because the skin of the new nail-fold is almost level with the nail-bed

"With the evolution of man, characterised as it was by delay in development, great prolongation of childhood and resultant consolidation of the family, this pattern of altruistic behaviour must have acquired enormously enhanced importance The size of the unit within which what may now be called ethical conduct prevailed grew larger, from the family to the clan, but between clans the sub-human competition on lines of natural selection persisted The same was true when the welfare unit became the tribe, and eventually the nation, but the relations between nations show only too clearly that there is still a step for man's moral evolution to take in enlarging the welfare unit to encompass the whole of humanity Man's moral evolution is still incomplete"—SIR GAVIN DE BEER, *The Listener*, July 3, 1958, p 12

ULCERATIVE COLITIS

A TEST OF PSYCHOSOMATIC HYPOTHESES

M SIM
M D Edin, D P M
CONSULTANT PSYCHIATRIST, UNITED BIRMINGHAM HOSPITALS

B N BROOKE
M D Birm, M Chir Cantab, F R C S
READER IN SURGERY, UNIVERSITY OF BIRMINGHAM

ULCERATIVE colitis has been claimed to be a member of the psychosomatic group of diseases According to Halliday (1943) a psychosomatic affection is "a bodily disorder whose nature can be appreciated only when emotional disturbances (i e, psychological happenings) are investigated in addition to physical disturbances (i e, somatic happenings)" Apparently some workers regard the case as proven

Sullivan and Chandler (1932) reported a series which they describe as of psychogenic origin, and Sullivan (1940) elaborated these findings with a paper on Psychogenic Factors in Ulcerative Colitis Groen (1947) discussed not only the psychogenesis of the disease but also the use of psychotherapy in its treatment, and this theme has been supported by Daniels (1942), Lindemann (1945), Karush and Daniels (1953) and Craddock (1953) In this country Wittkower (1938) described personality studies in 48 unselected cases and found evidence that "ulcerative colitis is a disease of the mentally ill or maladjusted Almost all the patients showed character disorders, obvious neuroses, or psychoses" With this view Paulley (1956) agrees

Several hypotheses have been advanced to explain the psychosomatic nature of the condition, and these are well reviewed by Engel (1955), who also illustrates (Engel 1954a, 1954b) the inadequacy of those hypotheses which depend on functional diarrhœa being a preliminary feature In his own series (Engel 1954b) of 32 patients 22 presented originally with bleeding, and diarrhœa, when it did occur, was usually secondary On the other hand, support for the "ejection-riddance" theories has come from Grace et al (1951) who, from their studies of 4 patients with fistulæ (2 with ulcerative colitis), conclude that "the colon of man is likely to participate in his reactions to threatening events in his life situation, including those threats which arise out of problems of interpersonal adjustment Changes involving colonic hyperfunctioning at first altogether functional and transitory may when unduly sustained result in structural change and disease"

Though agreeing that personality changes are seen in patients with ulcerative colitis, many do not regard these changes as primary They adopt a "common-sense" view that a person with frequent diarrhœa and bleeding per rectum may well show secondary personality changes, if this were so it would prove a most powerful argument against the psychosomatic theorists Two of the more attractive hypotheses—those of Alexander (1952) and Grace et al (1951)—largely depend on diarrhœa being a reaction to frustration, and, since this symptom has been shown by Engel (1954b) to be the less common presenting feature of the disease, there is good reason for further inquiry into a larger series

Method

A retrospective inquiry into the incidence and order of appearance of each of six main symptoms was undertaken by means of a questionnaire, which was circulated to all 164 members of the Midlands division of the Ileostomy Association 142 replied, and we attribute

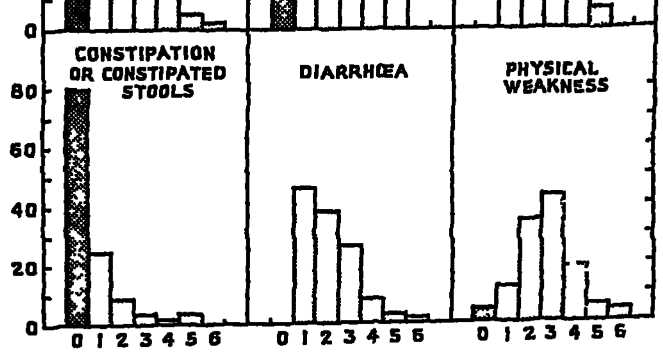
INCIDENCE OF EACH SYMPTOM IN ITS ORDER OF APPEARANCE, LAST COLUMN SHOWS NUMBER OF PATIENTS WHO DID NOT HAVE THE SYMPTOM

Symptoms	Order of appearance						0
	I	II	III	IV	V	VI	
Abdominal pain	23	33	17	16	5	2	25
Anxiety and/or depression	23	16	33	21	13	—	14
Bleeding per rectum	37	48	18	10	6	—	—
Constipation or constipated stools	24	9	3	1	3	—	80
Diarrhœa	47	39	27	7	2	1	—
Physical weakness	5	12	35	43	19	5	4
Total	159	157	133	98	48	8	—

this high return to the fact that the form, though designed by ourselves, had been approved by the secretary of the association and sent out to the members by their officers with an explanatory letter

There are disadvantages in this method, for retrospective surveys are less satisfactory than those planned in advance, and in this particular investigation reliance has to be placed on the memory of patients for symptoms which in about a third of the series had begun five to ten years before We did consider the perusal of case-histories, but soon realised that, no matter how good these may be, a great difference exists between information obtained by various doctors and a standardised series of questions designed to produce answers in numbers We chose the questionnaire, not only because of the greater ease in handling the data derived, but because we wanted to test the method itself The active cooperation of a patient in a therapeutic trial has already been reported by Hogben and Sim (1953), and an Ileostomy Association with a membership of 164 consisting mainly of patients whose diagnosis had been confirmed at laparotomy appeared to us a most suitable medium for this type of investigation

Of the 142 forms returned, 1 was unsigned Confirmation of the diagnosis was sought from the surgeons concerned in all cases and was obtained in all but 3, a further 6 had not had ulcerative colitis Of the 132 who had, 12 returned forms completed in an equivocal manner, and though we had access to most of the information from other sources, we wanted to confine the investigation to data derived from the questionnaire, these were therefore excluded from the study The replies from 120 patients form the basis of this report and are recorded in the accompanying figure



Order of appearance of 6 symptoms in 120 patients with ulcerative colitis

Analysis of Data

Diarrhœa as a presenting symptom is only slightly more common than bleeding (47 37, see table), and therefore the "ejection-riddance" theory finds only very modest support On the other hand, bleeding presents initially more commonly than most psychosomatic theorists would have us believe, perhaps therefore an alternative hypothesis is needed Engel (1955) has elaborated one, but, since it depends on the fact that bleeding is the prime feature in the majority of cases, it cannot be considered adequate for the majority of the present series He does, however, stress that with a careful personal analysis of data (Engel 1954b) more patients admit to bleeding as a first symptom than to diarrhœa, and it may be that the questionnaire did not supply this information accurately This is a valid argument, but the value of the present method cannot be adequately tested by argument, but only by a carefully controlled prospective inquiry, which we propose to do

Anxiety and depression are traditionally regarded as important precipitating factors in the illness, yet they provide the first symptoms in only 23, these conditions are so common in the general population that this may be a chance finding On the other hand it is quite clear that affective disturbances are more frequent as third and fourth symptoms, lending some support to the "common-sense" view that the mental changes follow the physical changes

Constipation appeared as a presenting symptom in Engel's series in 14 of his 32 patients This is very different from the proportion in our series (24 out of 120) which seems to represent the subgroup whose disease started as proctitis or procto-sigmoiditis A more striking feature regarding this symptom is the large number (80) who have not listed it at all

Summary and Conclusion

A method of inquiry into the presenting symptoms of ulcerative colitis is described, making use of an association of patients known as the Ileostomy Association

Diarrhœa as an initial symptom is only slightly more common than bleeding There is little evidence therefore to support existing psychosomatic hypotheses of the origin of the disease

Anxiety and depression are commoner after than before diarrhœa and bleeding

This inquiry could not have been made without the fullest cooperation of the Midland Ileostomy Association, and we should like to record our sincerest thanks to the members, and to all those surgeons who kindly answered our inquiry regarding diagnosis of their patients

Preliminary Communications

MULTIPLICATION OF RAT-LEPROSY BACILLI IN CULTURES OF RAT FIBROBLASTS

FOR many years experimental rat leprosy has been studied as a model of the human disease. Both are chronic infections caused by mycobacteria in which the bacilli exist as obligate intracellular parasites of mononuclear cells. Until recently neither causative organism has been cultured. Because of the intracellular existence of the bacilli in vivo our attempts to grow rat-leprosy bacilli (*Mycobacterium lepræmurium*) have been made using tissue cultures.

Rees and Wong[1] have recently reported from these laboratories that significant though limited multiplication of *Myco. lepræmurium* can occur in cultures of spleen tissue obtained from previously infected animals. Substantially similar results in spleen cells have been reported by Wallace and his colleagues[2]. Suggestive evidence of multiplication has also been obtained by Hawking[3] using rat monocytes. The successful demonstration, for the first time, of unequivocal multiplication of *Myco. lepræmurium* in tissue culture has been greatly facilitated by the development and use of precise methods for determining the total number of bacilli present in the cell cultures before and after cultivation.[1,2] Previous methods of detecting multiplication, which have depended on the distribution of bacilli in tissue cells, are open to serious error because of the redistribution of bacilli that inevitably occurs in a changing and often diminishing cell population.

Undoubtedly primary cultures of explanted tissue from previously infected animals offer the greatest chance of success, because the bacilli remain undisturbed in the specific host cells. On the other hand such cultures cannot be maintained in a healthy state for the long-term studies required to obtain continuous multiplication of a slowly growing organism like *Myco. lepræmurium* (mean generation time 13 days[4,5]). Such studies require the use of an established line of cells that can be infected with bacilli in vitro. We first tried Earle's L strain of mouse fibroblasts, and, although these cells can be successfully parasitised by *Myco. lepræmurium* in vitro, no multiplication of bacilli was observed in cultures maintained for 46 days. Wallace et al.[2] found the same with L-strain cell cultures, but when the metabolism of these cells was modified by the addition of high concentrations of hydrocortisone limited multiplication of bacilli resulted. It has been our experience that the concentration of hydrocortisone used severely damages the cells, and that the conditions are therefore unsuitable for obtaining continuous multiplication of bacilli.

We have now successfully initiated multiplication of *Myco. lepræmurium* in a strain of rat fibroblast cells without hydrocortisone.

METHODS

Partially purified suspensions of *Myco. lepræmurium* in 5% albumin in saline or in 5% albumin and 5% yeast supplement in phosphate buffer, were freshly prepared for each experiment from the livers of mice infected intravenously 8–12 weeks previously. The suspensions were adjusted to contain approximately 5×10^{10} bacilli per ml. All procedures were carried out in the cold (2–4°C).

Cultures of the 14pf strain of rat fibroblasts[6,7] were maintained in medium containing 50% human cord serum, HCS$_{50}$, and 50% Hanks balanced salt solution, BSS$_{50}$, or HCS$_{50}$ BSS$_{50}$. For each experiment cultures of cells were grown for 7–10 days in 'Pyrex' feeding-bottles, in medium containing only 25 units penicillin per ml and no streptomycin. The medium was withdrawn and the cells carefully washed with an excess of BSS to remove free serum. The cells were then infected by adding to each bottle approximately 10^9 freshly prepared bacilli suspended in 0·0125% albumin in BSS and incubating at 37°C for 24 hours.

Under these conditions the cells remained healthy and readily ingested bacilli which were not directly exposed to the possible toxic effect of serum[8]. On an average approximately 90% of the cells were infected with bacilli as follows: 1–2 bacilli, 15%; 3–5 bacilli, 22%; 6–10 bacilli, 21%; and over 10 bacilli, 31%.

The infected cultures were trypsinised and the cells thoroughly washed in BSS to remove the extracellular bacilli. The cells, after centrifuging, were resuspended in medium (usually HCS$_{50}$ BSS$_{50}$ and 25 units penicillin), carefully maintained in suspension by agitation and rapidly distributed in 1 ml. samples containing approximately 10^5 cells, into pyrex culture tubes. In most of the experiments the tubes were divided into two groups: (a) no addition of antileprous drugs, and (b) addition of 100 γ streptomycin and 0·1 γ isoniazid—a combination expected from chemotherapeutic observations of rat leprosy[9,10] to inhibit growth of organisms in vitro, and so serve as an essential control. Before incubating the cultures at 34 or 37°C, three tubes were set aside for counting the total number of bacilli per tube. The medium was changed every 11 days and retained for counting. Any serious fall in pH or deterioration in the quality of the cells was rectified by the addition of drop quantities of 1·4% sodium bicarbonate or chick-embryo extract, respectively. Three tubes were set aside from each group for counting bacilli on day 13, 26, and 39.

To count accurately the total number of bacilli present in each culture it was first necessary to release completely the bacilli from the cells and so obtain a well-dispersed suspension of organisms. This was achieved in a single operation by exposing the culture tubes to ultrasonic vibration for 15 sec. (Mullard ultrasonic generator type E 7562, frequency 340 Kc. per sec., power 200 watts), a procedure that has been shown to disrupt the cells completely without damage to the intracellular bacilli[11]. Using a modified Breed technique,[12] smears were prepared from a known volume of the disrupted cell cultures, spread over a standard area on a microscope slide and stained by a modified Ziehl-Neelsen method. A count was made of acid-fast bacilli present in equivalent standard samples from each culture. Successive fluid changes from each culture were pooled and counted after similar treatment.

RESULTS

The results of the counts obtained from 9 experiments are shown in the table.

MEAN NUMBER OF ACID-FAST BACILLI COUNTED IN STANDARD SAMPLES FROM CULTURES

Experiment	Group	No. of bacilli				Maximum increase (ratio)
		Day				
		0	13	26	39

Each mean count of acid-fast bacilli was obtained from a pool of three cultures, from which 2 or 4 spreads were made and each counted in duplicate In 8 out of 9 experiments the results show a significant increase in the number of bacilli present after incubation in the cultures without streptomycin and isoniazid There was no significant increase in the number of bacilli in cultures containing high concentrations of the drugs In 4 experiments a group of cultures containing hydrocortisone was included because of the report[2] that *Myco lepræmurium* only multiplied within L-strain cells in the presence of the hormone From our results it can be seen that hydrocortisone is not essential for the multiplication of bacilli in 14pf cells In general the initial rate of multiplication corresponds closely to that obtained in vivo in the mouse In some experiments multiplication was almost entirely limited to the first 13 days of incubation, whereas in 3 experiments there was a more continuous increase in the number of bacilli recovered from cultures maintained for 39 days In these experiments the bacterial populations increased approximately 5 5, 4 4, and 3 1 fold, representing significantly greater multiplication than has been obtained in spleen cultures or L-strain cells plus hydrocortisone

Although these results are encouraging, the multiplication obtained is either limited to the initial 13-day period of incubation, or, where it has been more continuous, the rate of multiplication has diminished This could be due to a deterioration in the quality of the cells, since the conditions (adopted primarily for accurate enumeration of bacilli) are not those most suited for providing good cell cultures On the other hand the cell type used for growing rat-leprosy bacilli is important because, using identical methods of assessment, multiplication did not occur in mouse monocytes,[1] in L-strain cells (without hydrocortisone), or in monkey-kidney cells[13] Initiation of multiplication of rat-leprosy bacilli in an established and unmodified line of tissue cells offers therefore, for the first time, a reasonable system in which to study the conditions required for continuous multiplication

We wish to record our thanks to Dr G O Gey for supplying the 14pf cultures and we gratefully acknowledge the technical assistance of Mr C V Gibbs and Miss M Collins

RESPONSE OF THE INFECTED URINARY TRACT TO BACTERIAL PYROGEN

THE difficulty of establishing the diagnosis of chronic pyelonephritis is well known An attempt has therefore been made to diagnose renal infection by a new and very simple method It seemed possible that the infected kidney might be in some way sensitive to parenterally administered bacterial products and that evidence of such sensitivity might be found in the urine

Changes in the excretion-rate of white and non-squamous epithelial cells in the urine after the intravenous injection of a bacterial pyrogen in 6 normal subjects were therefore compared with those in 10 patients in whom the diagnosis of chronic renal infection was regarded as established beyond reasonable doubt

The controls were 6 normal healthy males who gave no history of urinary tract infection at any time The urine of all was free of protein and showed a normal excretion-rate of white and non-squamous epithelial cells

In the 10 patients, the diagnosis of renal infection was made either on histological evidence obtained from renal biopsy, nephrectomy, or necropsy, or on evidence afforded by a combination of the history, or the presence of nitrogen retention in the absence of any other discoverable cause, with the radiological demonstration of nephrolithiasis, deformities of the pelvi-calycine system, or gross deformities of the renal outlines shown by presacral pneumography Some patients, in addition, had infected urines and nearly all had abnormal cell-excretion rates when first seen

METHODS

The rate of urinary cellular excretion was determined by the method of Houghton and Pears[1] Three specimens of urine were collected at hourly intervals before the intravenous injection of 0 007 γ per kg body-weight of 'Pyrexal' (Wander), a purified lipopolysaccharide derived from *Salmonella abortus equi* Four specimens of urine were collected at thirty-minute intervals, starting from the time of collection of the last control specimen The rate of excretion of white and non squamous epithelial cells was determined on each of these seven specimens The deposit obtained from 10 ml of each specimen was stained by Gram's method to demonstrate organisms From all female patients the urine was collected through an indwelling urethral catheter

Clearances of inulin and *p*-aminohippuric acid were determined using a constant-infusion technique Inulin was determined by a modification[2] of Harrison's method[3] and para-aminohippuric acid by the method of Smith et al[4]

Temperatures were taken in the mouth by clinical thermometer

RESULTS

In each of the patients and the controls, the difference between the means of the cellular excretion-rates in the three preinjection periods and the first two postinjection periods were calculated From these differences for each individual, the mean differences for each group were derived and expressed as a percentage of the mean preinjection value for that group The result for the controls was −10 2%, for the patients it was +186 2% The probability of obtaining such a result fortuitously is less than one in a hundred but more than one in a thousand $(0\ 01>\mathrm{P}>0\ 001)$

There appears to be no correlation between the urine flow and the rate of cellular excretion In two patients, inulin and *p*-aminohippuric clearances showed that the excretion-rate of cells in the urine increases without any change occurring in the glomerular filtration-rate or the effective renal plasma flow In all patients, the rise in cellular excretion occurred within thirty minutes, and thus a considerable time before the onset of rigor or fever in some, the excretion-rate fell as the temperature rose Cortisone and aspirin appear to modify profoundly the expected changes in the urinary excretion of cells in all the cases so far studied from this point of view In some patients, bacteria appeared in the urine after the injection of pyrogen when they had been absent before it in other cases, where bacteria were already present, their number increased greatly after the injection

A case of acute focal nephritis, proven by renal biopsy, a case of the nephrotic syndrome, and a case of the malignant phase of essential hypertension, all with initially abnormal urinary cell excretion rates, failed to show any change in their rates after the injection of pyrogen All developed a fever

Work is continuing in an attempt to elucidate the mechanism of this response of the infected kidney to a substance of bacterial origin injected intravenously, and to demonstrate conclusively whether or not it is in fact specific for cases of renal infection At present, it seems permissible to suggest that the phenomenon is one of hypersensitivity of a site of infection to parenterally administered, heterologous bacterial products, and that it thus bears obvious resemblances to that described by Sanarelli[5] and by Shwartzman[6]

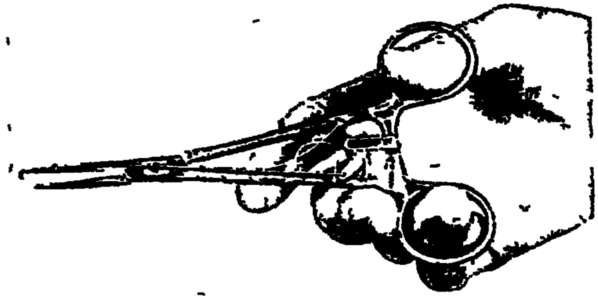
New Inventions

A PRECISION CLIP APPLICATOR

FOR several years I have been using a silver clip applicator that includes a hook which automatically pulls the vessel into an exact position for occlusion by the limbs of the silver clip The action of the mechanism for primarily drawing the vessel into position is an integral part of the clip applicator and works synchronously with the approximation of the silver clip limbs (see figure) The mechanism is so designed that the hook completes its action, drawing the vessel into position, before the clip has closed more than ten per cent



Precision clip applicator in open position

I have used this clip applicator mostly in occluding major branches of the circle of Willis in order to trap aneurysms It has been used for getting behind aneurysms and drawing their neck into a precise position within the clip The instrument has been found quite useful for holding and clipping the stalk in pituitary-stalk sections or hypophysectomies With it the identification of the stalk and pulling it into position within the silver clip are straightforward

With the usual applicator the clip may not be applied properly unless the vessel is dissected free and lifted away from the brain tissue, or unless the applicator is pressed against the tissue to force the vessel within the clip This instrument has been found useful not only in dissecting out the vessel from the pial and arachnoidal attachments but also in automatically lifting the vessel a millimetre or two away from the tissue surface for precision clipping, the principal contact being with the vessel occluded The instrument has also been found useful for precise clipping in deep small openings where depth perception is difficult. By use of the hook, the vessel can be properly oriented to the clip and mechanically drawn into the proper position for clipping A standard MacKenzie clip-rack can be used by merely grinding off the foot of the rack on the hook side, which allows the hook to drop down so that the tips of the clip applicator can assume their usual position

No serious disadvantages have been found in the use of this clip applicator except that caution must be exercised, as with any surgical instrument, when advancing into or coming away from the wound

I wish to thank Mr J A Jones, machinist, for his assistance in the making of the pilot instrument

Reviews of Books

Sir Charles Bell

His Life and Times SIR GORDON GORDON-TAYLOR, K.B.E., C.B., F.R.C.S., consulting surgeon, Middlesex Hospital, London, E. W WALLS, M.D., B.SC., F.R.C.S.E., S A Courtauld professor of anatomy, Middlesex Hospital Medical School. Edinburgh E & S Livingstone 1958 Pp 288 42*s*

WITH characteristic vigour, Sir Gordon Gordon-Taylor has chosen to mark his 80th birthday by collaborating with Professor Walls in the production of an erudite and intensely interesting study of their great predecessor at the Middlesex Hospital. When Charles Bell first came to London, in 1804, he was already widely known as the author of two anatomical textbooks Two years later the appearance of his *Essays on the Anatomy of Expression in Painting* revealed him not only as an expert anatomist but also as one possessed of the "most exquisite taste and feeling for sculpture and painting" In due course he was appointed surgeon to the Middlesex Hospital, and published the first of the series of papers upon the structure and function of the nervous system for which he is chiefly remembered today—and round which was waged his unhappy controversy with Magendie of Paris

In any age, Bell would have provided material for a lengthy and valuable biography, but he also lived in a period of great political, military, and intellectual excitement. (When Waterloo was fought, Bell crossed to Brussels and worked among the wounded for three days, with scarcely as many hours' sleep) His contemporaries were such men as Abernethy and Astley Cooper, Syme and Dupuytren, and an important characteristic of this book is the way in which Bell is at all times shown in relation to a carefully detailed background (It is strange, though, that no mention is made of Abraham Colles, who was born the year before Bell, and died a year later Like Bell, he graduated at Edinburgh and, like him, was hospitably received by Astley Cooper when he moved to London.)

A useful appendix of 90 pages includes a reproduction in its entirety of Bell's *Idea of a New Anatomy of the Brain*, and much hitherto unpublished correspondence about him. Appendices usually go unread, but this one, with its notes about the Resurrection Men, the Waterloo casualties, and Bell's first cases of the palsy which perpetuates his name, is likely to engage and reward the reader's interest as much as the fascinating pages which precede it.

High Arterial Pressure

F H SMIRK, M.D., F.R.C.P., F.R.A.C.P., professor of medicine, University of Otago, Dunedin, New Zealand Oxford Blackwell Scientific Publications 1958 Pp 764 75*s*

FOR many years Professor Smirk has studied patients with hypertension, and his wide experience is set out in this comprehensive volume.

In the early chapters he introduces the concept of the "basal blood-pressure", the importance of which becomes increasingly clear later Succeeding chapters are concerned with, inter alia, the natural history of hypertension and the effect of environment on the blood-pressure, and the clinical manifestations of hypertension and the physiology of blood-pressure regulation Experimental hypertension is covered fully, and an excellent chapter on the pathogenesis of high blood-pressure—dangerous ground skilfully negotiated—prefaces the chapter dealing with treatment Professor Smirk assesses all the well-known and several less well-known hypotensive agents and procedures carefully and fairly, though he leaves no doubt as to his own preference for ganglion-blocking agents The management of patients with hypertension is discussed usefully in great detail Precise details of certain aspects of treatment are contained in six appendices, and a seventh covers, with admirable brevity, papers published late in 1956 and in 1957 during the printing of the book.

Professor Smirk has provided from his own experience and from a comprehensive survey of the literature both a work of reference and a book which should be read by all clinicians undertaking the care of patients with high arterial pressure

Tumours of the Soft Somatic Tissues

GEORGE T PACK, M D, LL D, F A C S, attending surgeon, Memorial Center for Cancer and Allied Diseases, IRVING M ARIEL, M D, F A C S, associate clinical professor of surgery and associate attending surgeon, New York Medical College London Cassell 1958 Pp 820 231s

EVERY surgeon, whether he works in a general or a specialised field, encounters from time to time a tumour which causes him more worry and doubt than half a dozen ordinary neoplasms Such a tumour is very often derived from "soft somatic tissues"—fascia, muscles, synovia, blood-vessels, or nerves—and there are several reasons why it poses special problems Sarcomas, synoviomas, and malignant neurilemmomas are rare, and few surgeons can draw on a considerable experience of them, pathologists sometimes give opinions about biopsy specimens at variance with the clinical features, and publications on them are found to consist largely of monographs listing a small number of cases not consistently treated No book at all has previously been published on this important group of tumours as a whole

The present volume, then, meets a real need It represents the experience of a group of internationally famous surgeons, who were for the most part dealing with the unrivalled material of the New York Memorial Center This is essentially a practical manual on the management of actual cases, and the authors are at pains to stress that many factors besides the histogenesis of the tumour must be considered when planning treatment The price may seem rather high But the volume is beautifully produced, and illustrated with five hundred excellent photographs and drawings The surgeon who buys a copy now will derive an unusual and pleasurable sensation from handling a book the title of which is likely to become very familiar in medical literature

Erythroblastosis Fetalis

FRED H ALLEN, JR, M D, clinical associate in pædiatrics, and LOUIS K DIAMOND, M D, associate professor of pædiatrics, Harvard Medical School Boston Little, Brown & Co London J & A Churchill 1958 Pp 143 30s

THIS short book is one of a series of collections of articles on medical progress originally published in the *New England Journal of Medicine*, the articles on which it is largely based were published in October, 1957 The book contains a remarkable amount of information and includes a useful glossary of technical terms A succinct account of the blood-group factors, including rare ones, is given, the mechanism of production of the syndrome is clearly discussed and diagnosis fully dealt with The technique the authors use for exchange transfusion is given in some detail In this country the tests and manœuvres described would all be carried out in the children's department of a hospital, and the finer points of blood-grouping are dealt with by the National Blood Transfusion Service centres Nevertheless all who deal with newborn children will find this book useful, and our only regret is that its price, excessive for this country, will keep it resting on the library shelf instead of in the resident's pocket

Obstetric Practice

H BRUCE WILLIAMS, CH M, F R A C S, F R C O G, lecturer in clinical obstetrics, King George V Hospital and University of Sydney Sydney and London Angus & Robertson 1957 Pp 168 25s

IN his handbook of abnormal obstetric practice (it does not deal with the normal) Mr Williams discusses the diagnosis and treatment of the complications of pregnancy and labour The brevity with which he has chosen to do this has necessitated some sweeping generalisations, for examples, "Endeavour to assess the size and weight of the child, for a very large child cannot be delivered by the vaginal route", "Remember that if you do a vaginal examination and can feel the sacrum, the diagonal conjugate is reduced, and therefore the child of normal size could not be delivered per vias naturales", "The patient may be a multipara with previous normal deliveries of normal sized infants, thus excluding pelvic contraction", and "The causes of fœtal distress during labour are (*a*) short cord, (*b*) prolapse of the cord" For those with little experience of obstetrics, such an approach is seldom suitable The classifications would not all meet with general favour thus the causes of habitual premature interruption of pregnancy are given as (1) diseased cervix, (2) no apparent cause, (3) other causes which are not diagnosed; and the causes of inversion of the uterus are grouped as (1) incorrect management of the third stage of labour, (2) spontaneous inversion, for example (i) pressure on the fundus of an atonic uterus or (ii) pulling on the cord

Although there is much that is interesting in Mr Williams' many original views, his book is unlikely to commend itself to teachers who favour a more orthodox text for their students

---

The Tissues of the Body (4th ed London Oxford University Press 1958 Pp 415 40s)—It is not quite twenty years since Prof W E Le Gros Clark's book first appeared, yet it can already be counted one of the classic texts of anatomy In this new edition he has pursued his policy of bringing to the notice of his students not only the tried principles and generalities of the subject but also some frequent glimpses of "the advancing front of scientific adventure" It is for this reason that this book is by far the best introduction to the study of anatomy It educates, stimulates, and evokes the critical spirit proper to youth Few anatomists of today could claim such a wide and up-to-date acquaintance with the multifarious activities of their fellows as can Professor Le Gros Clark His book is, indeed, not merely a superb introduction for the novice in anatomy, but almost equally valuable to the professional as a periodic review of progress in the subject

Clinical Heart Disease (5th ed London W B Saunders 1958 Pp 673 66s 6d)—This excellent book by Prof Samuel A Levine, of Harvard, has expanded greatly since it was first written in 1936, but it has remained a great favourite both with medical students and physicians It was practical, clinical, eminently readable, and not too long Unfortunately, it had lately become out of date, and it is a pleasure to find that this has now been remedied Two sections have been added, both by well-known authors and both excellent One is on congenital heart-disease by Dr Alexander Nadas, cardiologist to the Children's Hospital at Boston and himself the author of a well-known book on congenital heart-disease His section is of only 32 pages, which seems small in a volume which has now been expanded to 673 pages, but that is perhaps the correct proportion for the adult cardiologist. The lack of illustrations in this section is disappointing, but it is in keeping with the rest of the book, except for the section on electrocardiography In this large section by Dr Harold Levine, who is in charge of electrocardiography at the Peter Bent Brigham Hospital, vectorcardiograms are shown and described with the electrocardiograms, but are difficult to "read" and are not married with the description of the electrocardiograms, as perhaps they should be in a textbook of this sort This is not the right book for those who like the physiological approach It is poor on the venous pulse, and auscultation sometimes does not receive the emphasis that one would expect from Professor Levine, especially in the section on acute rheumatic carditis Nevertheless the text can be read and enjoyed, and remembered by its good clinical sense and anecdotes in a way that is most unusual in a specialised monograph

Spinal Anesthesia (Springfield, Illinois Charles C Thomas Oxford Blackwell Scientific Publications 1958 Pp 61 22s 6*d*)—Prof John B Dillon, of the University of California Medical Center, here presents a very concise account of the essential practical facts concerning spinal anæsthesia He has written it for residents in anæsthesia and for those who practise spinal anæsthesia but who have had neither the time nor the opportunity to explore some of its aspects He provides a useful introduction for residents, but the book is unlikely to appeal to those who practise anæsthesia, because it does not attempt to appraise deeply the physiological and pathological implications of the technique

THE LANCET

LONDON 19 JULY 1958

Bacterial Endocarditis

BEFORE the introduction of chemotherapy bacterial endocarditis was almost invariably fatal, but even today probably one in every four patients succumbs FRIEDBERG[1] has shown that this is due mainly to delay in treatment arising from errors in diagnosis, and to the inadequate treatment of patients with resistant organisms Patients over the age of 40 and those with persistently negative blood-cultures[2] have an appreciably greater mortality Treatment should be started at the earliest suspicion—unexplained fever, anæmia, splenic enlargement, or changing murmurs, accompanying a cardiac lesion Eradication of organisms deeply buried in vegetations depends on their being reached by adequate concentrations of an antibiotic to which they are sensitive, and as host defence mechanisms are virtually impotent in these situations, the antibiotic must be bactericidal rather than bacteriostatic[3] EAGLE et al[4] have shown in experimental lesions that the rate of destruction of organisms by penicillin depends on their susceptibility and the total time that an effective concentration is maintained at the site of infection, the greater the number of organisms, the longer must be the treatment EAGLE et al[5] also deduced that in their experiments a serum level five to twenty times the minimum inhibitory level in vitro was required, and it is likely that even higher levels are required in bacterial endocarditis to ensure diffusion into the vegetations Such levels cannot be attained with depot preparations The failure of penicillin in adequate doses to cure some patients, even though the organisms are sensitive, may be the result of a heavy concentration of organisms in the vegetation[4], in these conditions organisms multiply only very slowly, and accordingly penicillin is largely ineffective The combination of penicillin with streptomycin has been shown in vitro by HUNTER[6] to overcome this difficulty, such a combination is highly bactericidal

FINLAND[7] has recently reviewed the present position regarding treatment Whenever possible the organism should be isolated, but there is little advantage in taking blood-cultures for longer than forty-eight hours since GRIFFITH and LEVINSON[8] found that 98% of positive results were obtained in this time Treatment should be started during incubation of the cultures, and the choice of antibiotic depends upon the probable organism Almost any organism can cause the disease, but *Streptococcus viridans* is easily the commonest, enterococci are more likely after genitourinary operations, and staphylococci after cardiac surgery FINLAND recommends penicillin whenever the organism is highly or moderately sensitive, but streptomycin should be added if more than 0 2 unit per ml is required for inhibition in vitro, and in all enterococcal infections None of the tetracyclines or chloramphenicol should ever be used alone where gram-positive organisms have been isolated, even when these are sensitive in vitro and despite occasional reports of cure, negative blood-cultures and clinical improvement may usually be obtained, but relapse almost always follows Streptomycin and erythromycin must never be given alone, for fear of resistance developing, and sulphonamides seem to have no place Short courses of treatment have been tried, particularly in the U S.A , and HUNTER and PATERSON[9] have reported a relapse-rate of only 6% in 146 patients treated for fourteen days with up to 12 million units of penicillin and 2 g streptomycin daily TOMPSETT et al[10] found that 24 patients out of 35 were cured after a similar period by 6 million units of penicillin and 1 g streptomycin daily, they regarded a further 8 as "probable cures" KELLOW and DOWLING[11] claim that a course of only ten days is necessary in infections with streptococci inhibited by 0 5 unit per ml ; but this hardly accords with general experience, and FINLAND prefers the recommendations of HUNTER and PATERSON Thus, when the organism is a highly sensitive streptococcus, inhibited by 0 1 unit per ml or less, a fourteen-day course may be given consisting of 2 million units of penicillin daily combined with 2 g streptomycin daily in the first week and 1 g streptomycin daily in the second Organisms sensitive to 0 2 unit per ml require 8 million units daily for two weeks followed by 4 million units daily for three weeks, combined with 1 g streptomycin daily If the organism is only sensitive to 1 unit per ml or more, the course should be 12 million units daily for three weeks and subsequently 4 million units for four weeks streptomycin 1 g daily is given throughout, and probenecid 0 5 g six-hourly is added to enhance penicillin blood-levels Isolation of an enterococcus demands this last programme as a minimum, and if the organism is relatively insensitive, up to 20 million units of penicillin daily is advisable, administered if necessary by constant intravenous infusion Staphylococci sensitive to 1 unit per ml are best dealt with by administering 12 million units of penicillin daily combined with probenecid for six weeks, and more resistant staphylococci must be treated simultaneously with two antibiotics to which the organism has been found moderately or highly sensitive Such combinations might be erythromycin or novobiocin with streptomycin, chloramphenicol, or a tetracycline, or chloramphenicol with streptomycin Bacitracin may be needed if the position is desperate. Probenecid blocks the excretion of penicillin only and is useless with other antibiotics For less common organisms, treatment can be planned only in the light of known sensitivity

Such recommendations may seem complex, but inadequate or misdirected treatment, while inducing a temporary quiescent phase, may also induce resistance in the infecting organism, and thus make ultimate eradication more difficult Early diagnosis or, preferably, prophylaxis [12] offers the best prospect If any doubt exists it is only prudent to prescribe the longer course, and in every case unremitting watch must be kept for any sign of relapse

Bone-marrow Transplantation in Blood Diseases

LAST year we drew attention to experimental work on the transplanting of bone-marrow to animals whose own marrow had been inactivated by exposure to radiation [13] These experiments had shown that, if suspensions of bone-marrow cells from healthy animals are injected intravenously into the irradiated animals, not only do a large proportion of the latter survive an otherwise fatal dose of irradiation, but also there is evidence that the donor cells proliferate in the host's marrow This discovery had been applied to the therapy of animals with transmitted leukæmia, they were exposed to a dose of X-radiation sufficient to destroy the bone-marrow, and then normal marrow cells were given, in some cases proliferating donor marrow replaced the former leukæmic marrow and the animals survived for some time The possibility of transplanting healthy marrow to patients with blood diseases has been explored with great energy The technique should be applicable to patients who have aplastic anæmia, or whose marrow has been rendered aplastic by exposure to radiation or by drugs such as nitrogen mustard or busulphan ('Myleran') given for the treatment of leukæmia, Hodgkin's disease, or similar conditions, or in an attempt to relieve the symptoms of malignant tumours Last October a conference on these matters was held at Boston, Mass , under the general chairmanship of Dr SHIELDS WARREN and Dr WILLIAM DAMESHEK, and the proceedings have been reported in *Blood* [14]

In the first session sources of bone-marrow and techniques for its preservation and administration were discussed L M TOCANTINS used ribs removed at thoracotomy operations, and he could get 10–15 specimens weekly, a 7–8 in length of rib yielded 6×10^8 to 6×10^9 cells, but he pointed out that, since adult cells are of little value to the recipient, the differential count should be known He also used marrow obtained from the vertebræ of cadavers, removed with sterile precautions within two hours after death WILLIAM MCFARLAND obtained marrow by aspiration from the posterior ilium with a Bierman needle [15], the marrow was aspirated into heparinised saline, and $1\text{–}4 \times 10^9$ nucleated cells were obtained from a single donor He also used cadaver marrow obtained from the sternum as well as the vertebræ E D THOMAS preferred marrow from fœtal sources when possible, $2\text{–}4 \times 10^9$ cells are obtainable from the four long bones, he forced the marrow through graded stainless-steel meshes [16] to obtain an even suspension of cells W H CROSBY and J AKEROYD had used whole-rib transplants, in these transplants the rib bone disappears and is replaced by fibrous tissue, and marrow later regrows within this fibrous tissue The bone-marrow suspension obtained from these various sources either has been given within three hours after preparation or has been preserved in glycerin by the Polge technique and stored at −70 to −80°C

The second session was devoted to the immunological difficulties when donor tissues are given to hosts that are not identical—difficulties that have often proved a bar to long-term survival C C CONGDON stated the problem shortly Normally mice live for 29–35 months, after lethal irradiation they die within ten days, but if given injections of healthy bone-marrow they survive and apparently recover But thirty to ninety days after irradiation followed by marrow treatment they begin to die, and all are dead by nine to ten months after exposure This late fatality is an immune reaction due to the presence of foreign bone-marrow T MAKINODAN recalled that mice given lethal irradiation can be protected by either mouse marrow or rat marrow, which proliferates under these circumstances [13] With rat marrow the late death-rate was increased and the animals showed a syndrome of loss of body-weight, increase of beta and gamma serum-globulins, and slow reaction to introduced antigens MAKINODAN suggested that there were good reasons for supposing that the late deaths were due to reactions of the host to the transplant, and therefore the amount of marrow injected should be kept to the minimum and as much extraneous tissue as possible should be removed J J TRENTIN pointed out that marrow used in these protection experiments can be autologous, isologous (same genotype as the recipient), homologous (same species but different genotype), or heterologous (e g , rat into mouse) The late-mortality disease occurs in mice protected with homologous or heterologous marrow, but not when isologous or autologous marrow The "heterologous disease" is more severe than the "homologous disease", and the homologous disease is worse with certain kinds of genotype incompatibility TRENTIN, unlike MAKINODAN, believes that the late fatality is due to reaction of the *donor* tissue, probably the transplanted lymphoid elements, against the tissue antigens of the otherwise tolerant host, and he points out that there is no secondary hæmopoietic depression and that skin grafts from the marrow donor into the host will persist TRENTIN also drew attention to an earlier type of mortality when high but sublethal doses of irradiation were followed by a dose of homologous marrow of the order needed to protect against lethal irradiation This earlier mortality is associated with secondary hæmopoietic depression and appears to be related to the ability of the host to reject transplanted homologous marrow—a sort of reaction that may well be observed in the clinical application of marrow transplantation

In the third session clinical results were discussed MCFARLAND reported on 6 cases of aplastic anæmia cared for by DAMESHEK's group Bone-marrow from posterior ilium was obtained from donors whose blood type was as near as possible to that of the recipient Each patient received one to three infusions a day for five to seven days, this meant using for each patient marrow from eight to twelve donors and taking between $0\;95 \times 10^{9}$ and 2×10^{9} cells per donor In one later case only one donor was used, large amounts of marrow being obtained from both posterior ilia Large doses of corticosteroids were given in order to reduce the immune reactions So far encouraging results have been obtained in all the patients Atkinson of Philadelphia mentioned the case of a child with acute leukæmia who was treated with radiation followed by marrow infusion, the donor being the patient's identical twin The child, who was also given corticosteroids before and during therapy, was " packed in rice and rotated to give equal exposure The entrance dose was calculated to be 400r and the exit dose 240r " The irradiation made the child very ill, and she was nearly dying when given an infusion of $2\;65 \times 10^{9}$ marrow cells In twenty-four hours the clinical condition was much improved, and in two weeks there was evidence of a remission, unfortunately this did not last long Kretchmer of Oak Ridge reported results with 2 cases of leukæmia which had relapsed after prednisolone treatment, the patients were given X rays followed by marrow infusion, and were very ill afterwards In 1 patient the marrow was obtained from the patient's mother, who had a different minor group antigen, several infusions were given The patient eventually improved somewhat, and some months later there was still evidence that donor cells were present Earlier, Tocantins had reported results of marrow infusions in 7 leukæmic patients whose own marrow had become hypoplastic after chemotherapy 2 patients had " notable cellular responses " He also mentioned a 16-year-old patient with terminal leukæmia and a low bone-marrow count who was given 150r total body irradiation followed two days later by marrow transfusions containing $5\;4 \times 10^{9}$ nucleated cells, there was a complete clinical and marrow remission which had persisted for four months at the time of the report

[16] Thomas, E D *ibid* 1955, 10, 600

A fourth session dealt with chemical compounds that protect bone-marrow from radiation, an aminoethylthicuronium compound was shown to enable larger doses of irradiation to be given safely to mice with localised lymphomas, with correspondingly greater reduction in the size of the tumours

Summarising, the report states that practical problems of obtaining, preserving, and administering marrow can all be worked out. But

> " the big ' catch ' in the whole thing was the immunologic reaction How could this be handled ? As yet no good technics had been evolved and it was probably best to proceed with the transplantation technics, learn as much as possible about them, and hope that tolerance for introduced marrow might be established and that anti-immune methods might be worked out Whether or not attempted destruction of leukæmic tissue (and normal marrow) followed by attempts at marrow repopulation had some chance of being successful remained to be seen At this writing, it seemed doubtful, not only because the leukemic tissue (or the proliferating stimulus) could not easily be overcome by radiation, but because the immunologic process was probably resistant to the doses of radiation that could be used in the human without fatality "

Heller and Yakulis[17] have lately described the case of a man with Hodgkin's disease whose marrow had become aplastic after the administration of tretamine (T.E.M.) He was given an intravenous injection of marrow pooled from four suitable donors The patient's genotype was O, M, CDe/cDe, four of the donors were N-positive and two were E-positive The treatment was followed by recovery, and N and E erythrocytes were still detectable in the peripheral blood ninety-eight days after the infusion, after that they declined and none of these foreign cells could be found a hundred and forty days later Heller and Yakulis remark that so far few similar reports have appeared This is true enough Thomas et al[18] reported 6 cases in September, 1957, their results were not impressive, a temporary " take " of the marrow transplant being found in only 2, but some of their patients were very ill and 3 died within fifty days from their primary disease Humble and Newton[19] gave marrow to 5 patients, but they were concerned only to show that such infusions were technically possible and had no immediate ill effects The reason for the paucity of reports may be found in the difficulties that were discussed at the Boston conference, and it is clear that marrow infusion is not a treatment to be lightly undertaken Ferrebee[20] estimates that from 2×10^{9} to 20×10^{9} nucleated marrow cells are needed for repopulation of the marrow space of a man But these reports show that, despite discouragements, the possibility of using marrow transplantation is being carefully studied, and already hopeful results have been obtained in aplastic anæmia

Preventable

This is the time of year when messages come from tankers in the Persian Gulf saying that some member of the crew is ill, or has died, from the effects of heat. The deaths may not be many, but they are very distressing, for the person who dies is usually a young man who a few days previously was in ordinary health In their paper this week Dr Leithead and his colleagues give a clear account of heat illness as seen when the patients are landed at an oil-town in Kuwait, and they explain where the dangers lie We earnestly hope that, with this additional evidence before them, the shipowners and Government authorities concerned will consider what more can be done to stop these unnecessary and tragically useless deaths

Of course a great deal has been done already Many tankers have cooling systems for messrooms and sick-bays, some now have air-conditioning of living quarters, and all must fulfil conditions of heat insulation laid down by the Ministry of Transport None, however, have yet achieved the special system of " tropicalisation " used in the Royal Navy Though amenities have so much improved, the short voyages from this country to the Gulf ports can still put a big strain on human adaptability to contrast After exposure to the coolness of an English summer, the crew may have hardly begun to adjust to heat before it strikes them (" like a sword ", as T E Lawrence said) when they leave the Suez Canal

On each voyage, acclimatisation must be achieved almost afresh, and there is a danger period, of a week or more, until the body has learnt to conserve salt by reducing the salt content of the sweat

Young men are casual, and a certain foolhardiness befits seafarers But these are poor consolations after a man has died because he did not bother to take extra salt at meals, or thought the suggestion soft Surely, people who make use of scientific discoveries, and live the new kind of lives that science has made possible, ought to be willing to listen also to what science says about the preservation of their health and safety in the new artificial environments? But the necessary knowledge needs to be supplied to them repeatedly and with conviction, and, though many senior officers are interested, they mostly lack time for promoting preventive medicine in detail Of course, if the ship has a doctor, he will be able to overcome irrelevant prejudices and make the crew understand that salt deficiency is something which anyone but a fool will take trouble to avoid But ships with fewer than 100 people on board do not have to carry a doctor

Dr Leithead and his colleagues suggest various ways in which the risks of these voyages could be reduced But there is another that leaps to the eye Granted that one cannot expect to have a fully qualified medical man in every vessel at sea, *why should there be this immense* difference between the medical care of 101 men, who *must* have a registered medical practitioner, and of 99 who need have nobody trained to advise them or attend wisely to those minor illnesses which in the tropics are so uncomfortably liable to become major? Many years have now passed since the Association of Sea and Air Port Health Authorities recommended that the smaller ships should each carry a sickbay steward We must *ask why this is not yet done*

Annotations

ORIGINS OF SOCIAL PSYCHIATRY

It is commonly believed that a real increase in mental breakdown is following on the raised tempo of modern life and our rapid cultural changes Unfortunately the statistics are still so fallible, and the boundaries of mental health and illness so hazy, that fact can scarcely be distinguished from fallacy—let alone from fantasy Some aspects of the "horizontal" approach, as it were, to culture and mental illness by G M Carstairs in his anthropological work were lately reviewed in these columns[1], and on July 8 at the Institute of Psychiatry, London, Prof George Rosen, of Columbia University, presented a "vertical" or longitudinal view

In a scholarly address he pointed out that the concept of sociocultural determination in mental illness is not by any means new Benjamin Rush studied the effects of the American Revolution on the participants being an ardent revolutionary himself, he noticed among his ranks an increase in health and happiness, the cure of hysterical disorders among the women, and blessings granted to previously infertile marriages Among those still loyal to the British, however, mental and physical breakdowns were common, and a particular type of hypochondriasis ("protection fever") was described After the peace of 1783, unwonted freedom led to a further form of insanity called by him "anarchia" Although French writers had noted mental accompaniments to their revolution, it seemed that Rush (though not entirely unbiased) could be credited with one of the *earliest attempts to establish a* causal correlation between social upheaval and mental *consequence*

This concept, as Professor Rosen explained, spread widely during the next century, and Rudolf Virchow in 1848 put forward a theory of "epidemic psychoses" indicative, he said, of major disturbances in man's life, and he distinguished between "artificial" (i e, social) and "natural" phenomena In the following year he carried the idea further, suggesting that mental and physical epidemics came and went at the turning-points of civilisation and could give us insight into the popular feelings of the time, but Griesinger regarded political change as an aggravating factor rather than a cause At about the middle of the 19th century the concept of the "rising tide of madness" came to the fore, and it was slightly comforting to realise that the pessimists of today were the descendants of such a long line of Jeremiahs On the positive side, a consequence of these views was an attack on the social structure itself with the aim of lessening the stresses therein Hawkes in 1857 argued for wide and enlightened social reforms Towards the end of the century a number of workers tried to provide a better factual basis by studying the incidence of insanity in different places and at different times, much evidence was in conflict, but the work of Durkheim on suicide was outstanding Unfortunately the great discoveries in pathology and bacteriology overshadowed this work, although interest in it was now active

Regarding future work, Professor Rosen concluded that certain social variables, such as wars, epidemics, or slumps, should be defined and studied at sociological, psychiatric, and physiological levels, and along the time axis He hoped that the historian, by clarifying issues in terms of their backgrounds and showing linkages not readily apparent, could make some contribution to the multidisciplinary approach Few would disagree with him

CONGENITAL MALFORMATIONS

It has been apparent for many years that the best way to study associations between events in the early months of pregnancy and congenital malformations is prospectively To go back into the pregnancy history after the birth of the malformed child is, in general, unsatisfactory, unless the investigation is carefully controlled This method led to an overestimate of the risk to the fœtus after rubella, Hill et al[1] now estimate from prospective studies that the risk of major defect is 50% in the first month, 25% in the second, and 17% in the third They suggest, however, that the risk may vary from year to year and between one country and another With careful controls, Stewart et al[2] have used the retrospective method more successfully in relation to malignant disease in childhood

[2] Stewart, A, Webb, J, Hewitt, D *Brit med J* 1958, i, 1495

One method of conducting a prospective inquiry is to use the records of maternity hospitals, listing the incidents recorded in pregnancy and then noting the result of the pregnancy. Carter[3] reported a study of this kind on about 15,000 deliveries in a London maternity hospital and found that none of the commonly recorded events in pregnancy were followed by a significant increase in the rate of malformation. There was a suggestion, however, that the rate might be higher after threatened abortion; and Turnbull and Walker[4] have since also found, though again not at a high level of significance, a greater rate after threatened abortions. Hospital records, while satisfactory for such items as mother's age and parity, inevitably give incomplete information about events early in pregnancy. The ideal is for a single trained observer to make special inquiry of the mother about the third month in pregnancy, and for this observer then to await the result of the pregnancy. The first general prospective study of this kind has now been reported by Dr Alison McDonald.[5]

McDonald interviewed 3295 mothers at the time of booking—this was mostly in the fourth or fifth month of pregnancy—at the Watford and St Albans clinics in 1952–55. She was able to discover the outcome of 3216 of these pregnancies. There were 72 miscarriages and 63 stillbirths. Nearly all the surviving infants were examined by doctors and the majority by a pædiatrician. Necropsies were performed on all but 8 of the stillborn and all but 4 of the 35 infants who died neonatally.

Major malformations were found in 50 (1·5%) and minor malformations in 72 (2·3%). These rates agree well with those in other series of booked cases (hospital series including emergency admissions naturally show a higher rate) in which the children are not followed beyond the neonatal period. For the minor malformations there was no association with any event early in pregnancy. This was true, too, for the major malformations and threatened abortions, extramarital conception, injury, fainting, uterine retroversion, rhesus incompatibility, marked anxiety, and emotional shock. The mothers of the children with major malformations had an above-average incidence in early pregnancy of fairly heavy work, acute febrile illness, active or quiescent pulmonary tuberculosis, and anæmia. Inevitably the number of mothers affected in these ways was small and the associations do not reach high levels of significance. It is noteworthy that the 6 mothers who had a specific fever early in pregnancy (pertussis in 2, mumps in 2, rubella in 1, infectious hepatitis in 1) all had normal babies.

This survey shows how far we are from having any idea of the cause of most congenital malformations. It is known that relatively few are essentially genetically determined, though for many there is evidence of genetic predisposition. Environmental factors must be playing some part in the causation of most malformations, but none of the common events in pregnancy, and only rubella and toxoplasmosis among rare events, have been convincingly incriminated. There has been much more success in relating certain common malformations to social class, maternal age, birth-order, geography, and season of the year. These, however, afford only indirect clues, and the primary environmental factors concerned in most malformations remain unknown.

CHRONIC IDIOPATHIC JAUNDICE

In 1954,[1] under the title a New Liver Disease, we drew attention to an apparently rare disorder of the liver reported independently by Dubin and Johnson[2] and Sprinz and Nelson.[3] In the past four years an additional 36 cases have been reported, bringing the total to 50—from which it may be inferred that the condition is by no means as rare as was at first thought by its discoverers. A summary of these 50 cases by Dubin[4] should prove a valuable basis for further work.

Dubin suggests that the fundamental defect is a genetically determined impairment of the excretory functions of the liver, which reveals itself clinically in intermittent attacks of jaundice with biliuria and sometimes pale stools. The onset may be insidious or acute, resembling an attack of infective hepatitis, or may follow some other disease or stress such as pneumonia, pregnancy, or immunisation. The attacks are usually associated with malaise, pain in the right hypochondrium, nausea, and vomiting and diarrhœa. Between the attacks the jaundice almost disappears, although in most cases the serum-bilirubin remains more or less increased. Laboratory investigations indicate an obstructive type of jaundice, since some 60% of the serum-bilirubin is of the direct-reacting variety and bile is present in the urine, and, although the serum-alkaline-phosphatase is rarely increased, there is little evidence of parenchymal damage and the serum-proteins are within normal limits. It is, therefore, hardly surprising that in 31 of these 50 patients laparotomy was undertaken for the relief of biliary obstruction; this was not found in a single case, although gallstones were present in 5. Of these first 50 patients only 9 were women, but, since the American Armed Forces Institute of Pathology was the chief case-finding source, the sex-distribution is obviously biased. The world-wide distribution of sporadic cases suggests that all ethnic groups are susceptible.

The morbid anatomy of the condition has been studied almost exclusively by biopsy, either by needle aspiration or laparotomy. The one outstanding abnormality is the remarkable colour of the liver—variously described as black, green, or mahogany—owing to accumulation in the centrilobular cells of large amounts of coarse yellow-brown pigment granules. These give histochemical reactions that identify them most closely with the lipofuscins, from which they differ mainly by their coarseness and persistence. Other hepatic abnormalities such as necrosis or fatty infiltration are rare and may be regarded as mainly incidental. Repeated biopsies with intervals of up to four years have shown no evidence of progressive hepatic injury, and this is confirmed by the complete lack of correlation between the duration of the disease and the intensity of the hepatic abnormality, as well as by the excellent prognosis as regards life expectancy.

The nature of the underlying dysfunction is still not precisely known. Since the greater part of the serum-bilirubin is of the direct-reacting variety the fault cannot be in the mechanism that converts bilirubin to its glucuronide, but is presumably in the mechanism of excretion that follows this conjugation. Other evidence of impaired excretion is obtained with bromsulphalein, and from attempts to display the gallbladder by oral cholecystography which were successful only once in 37 patients The highly characteristic accumulation of pigment in the liver cells is presumably also the result of impaired excretion since the liver normally excretes lipofuscin pigment [5,6] The biochemical steps of these various excretions are still almost unknown, and it may reasonably be hoped that much will be learnt from further studies of these cases of chronic idiopathic jaundice

PULMONARY ALVEOLAR PROTEINOSIS

KNOWLEDGE of pulmonary pathology has been greatly extended in recent years For instance, interstitial pneumonia due to infection with *Pneumocystis carinii* has been firmly established as an entity with characteristic histopathological changes, and progressive interstitial fibrosis of the lungs (Hamman-Rich disease) and alveolar microlithiasis have been thoroughly investigated Now a new pulmonary disorder has been described by three distinguished pathologists from the Harvard Medical School, Yale University, and the Armed Forces Institute of Pathology [7] Rosen et al name the disease "pulmonary alveolar proteinosis", and their conclusions are based on study of biopsy material from 27 patients 8 died, and in 7 of these necropsy material was available

There was only 1 child affected, almost all the patients were aged 20–50, and males were two and a half times as commonly affected as females The disease is chronic and its onset insidious, in some cases it is heralded by a short febrile illness, but in others there is no fever Progressive dyspnœa and a cough, which is usually productive, are the presenting symptoms Physical signs are few and, apart from neutrophil leucocytosis, which is common, laboratory findings have not proved informative X-ray examination shows at the height of the illness a "fine, diffuse, perihilar, radiating, feathery or vaguely nodular, soft density" with a "butterfly" distribution The disorder may be confused with sarcoidosis, though the hilar lymph-nodes are apparently not involved Rosen et al found on histological examination that the terminal air-spaces were filled with granular or homogeneous eosinophilic material which was strongly positive to periodic acid/Schiff (P A S) The P A S reaction was reversibly blocked by acetylation but was unaltered by saliva digestion The material stained pale blue with Hale's reduced iron method, and was metachromatic, and the metachromasia was increased by sulphation The presence of a polysaccharide was thus well established Lipids were demonstrable in frozen sections by Sudan and oil-red-O Cholesterol was present but phospholipids were apparently absent A protein component was revealed by a weak Millon reaction Rosen et al term the material "proteinaceous" and consider it to be the result of transformation of septal cells which increase in number and size In all cases laminated, strongly eosinophilic, and P A S -positive intra-alveolar bodies, 2–30 μ in diameter, were seen Some of these stained deep blue with phosphotungstic-acid hæmatoxylin, and none was calcified Rosen et al believe that, when septal cells disintegrate, they may form a nidus for deposition of proteinaceous material and thus the formation of the laminated bodies Cellular infiltration of interalveolar septa was absent or minimal The honeycombed masses which are so characteristic of pneumocystic pneumonia were not seen in pulmonary alveolar proteinosis The disorder is quite distinct from pneumocystic pneumonia and from microlithiasis alveolaris Extensive bacteriological, virological, and serological investigations failed to disclose an organism responsible for the disease On the other hand case-histories and histological findings suggest that the cause is inhalation of some irritant substance Neither antibiotics nor corticoids have proved conclusively beneficial Spontaneous improvement was not unusual, but, although some of the patients were observed for several years, in only 1 instance was clinical recovery associated with disappearance of radiographic signs

HISTAMINE HEADACHE

FOR almost a century a type of episodic headache has been recognised in which unilateral pain is accompanied by ipsilateral nasal congestion, conjunctival suffusion with lacrimation, and often erythema of the face It has usually been regarded as a variant of migraine In 1939 Horton et al [1] described it again and pointed out that it could often be precipitated by injection of histamine In subsequent papers Horton suggested that it was due to abnormal sensitivity to histamine and could be cured by graduated desensitisation

There is no doubt that such a discrete clinical entity exists within the group of episodic unilateral headaches The condition is commoner in men than in women, and more recent descriptions [2,3] have added to the syndrome a tendency for the headaches to occur in groups Thus they may come on several times a day, sometimes mainly at night, for a few weeks and may then be absent for weeks or months If histamine is administered during a bout of attacks it rarely fails to provoke one, but between times it may not do so Nevertheless the specific causal role which Horton assigned to histamine, and the benefits he claimed for histamine desensitisation, have not been widely confirmed Some cases are substantially improved for a long time, but many soon relapse, and in some repeated desensitisation has no effect Moreover antihistamines also usually prove valueless in treatment On the other hand ergotamine tartrate commonly aborts an attack, especially if given early, and Symonds [3] has claimed good results from administration of prophylactic intramuscular ergotamine at times when a series of attacks is known to be imminent, such prophylaxis is often practicable because in many cases the attacks have a fairly fixed time of onset in the twenty-four hours In a review of 20 cases Robinson [4] recommends ergotamine, if feasible prophylactically, as the best treatment—though he still prefers to differentiate the syndrome from migraine It is doubtful whether this distinction can be maintained The precise nature of migraine still escapes us, though its end-result as a localised vasomotor disorder is more clearly understood, but there is nothing which excludes the so-called histamine headache as a variant of migraine Indeed it would seem reasonable to regard it as one of those varieties which are triggered by allergens—a view supported by its seasonal incidence in some cases

Congresses

CANCER

THE Seventh International Cancer Congress (under the auspices of the International Union against Cancer) was held in London from July 6 to 12, under the presidency of Sir STANFORD CADE The first of these conferences was held in London thirty years ago At that time no pure carcinogens were known, no hormone had been isolated in the pure state, and no inbred strain of mouse was available in this country In the intervening years a vast amount of work has opened new ways of approach which are reflected in the membership of approximately 2500 persons and in the variety of subject treated in the 600 papers which were presented To those who knew the earlier conferences it is strange that so little time should be devoted in this one to descriptions of new carcinogens and to pathological anatomy The emphasis is much more upon mechanisms than upon causative agents, and there is a noteworthy attempt to relate experimental work to the disease in man Outside the laboratory the the epidemiological approach is increasingly to the fore

Epidemiological Studies in Cancer

As Dr PERCY STOCKS (Britain) said to the section on population studies, the epidemiology of malignant disease can be approached through three main avenues (1) the vital statistics of mortality from cancer of specific types in different sections of the population grouped according to the information given at the time of a national census, (2) morbidity-rates based on some system of notification and registration of cases, usually in the catchment area of cancer-treatment centres, and (3) special surveys, either retrospective or prospective, of particular subgroups in the population

All these methods were exemplified in reports to the congress, and their general intention was to relate the onset of malignant change to environmental circumstance or personal characteristics or habits such as age, sex, race, diet, and smoking Since, strictly speaking, we are concerned with the factors which favour the onset of cancerous disease, Dr Stocks believes that attention should be concentrated on "inception"-rates based on the date of the onset of symptoms and signs of the cancer rather than on the conventional "incidence"-rates based on the year and age of either registration or death He has used this approach in his own studies in a five-year survey of the Liverpool hospital region and North Wales—an area with a population of some 2$^1/_2$ million

Inception-rates were derived from death registration, where the certification of cause of death was checked by comparison with hospital and necropsy records, as well as from admissions to hospital These inception-rates could thus be related to the various characteristics of the population in the area classified either in the usual way by age, sex, occupation, and housing, or according to the results of interviews with the patients themselves and a group of "controls" matched by age Where the patient had died, health visitors elicited from relatives histories which, when checked against the responses given by some of these patients while in hospital, proved surprisingly accurate At the same time, collaboration with the Medical Research Council and the Fuel Research Station allowed estimates to be made of the concentration of certain polycyclic hydrocarbons, trace elements, sulphur dioxide, and total smoke in the air at different points in the region In the same way, samples of the soil in the gardens of patients who had died from cancer and corresponding controls were analysed for certain chemical characters and trace elements[1] Cancer of the lung, although exhibiting the usual relationship to smoking, also appeared to be associated with local air pollution levels

Dr P F DENOIX (France) observed how vital-statistical rates could be used to compare the varying trends in mortality from cancer of the breast and uterus in different countries in recent years In general, there seems to be a tendency for a concurrent increase in the death-rate from breast cancer and a decrease in the rate for cancer of the uterus

Dr E PEDERSEN, of the Norwegian Cancer Registry, illustrated the value, actual and potential, of the efficient system of cancer registration which has been built up in his country since 1952 The records give a strong hint that such schemes, designed to stimulate interest in cancer detection, can bring cases to notice earlier, but the diagnostic cross-checks also give a useful warning against a too literal interpretation of apparent urban/rural differences in cancer mortality On the other hand, the registration system has revealed geographical trends in mortality, such as a gradual increase in cancer of the thyroid from south to north, which are unlikely to be explained by regional differences in diagnostic facilities and skills

Dr Pedersen also described how in Norway advantage has been taken of the work of the Norwegian Cancer Society to elicit, by specific questions, data on menstrual and reproductive histories for a large number of presumably healthy women, whose subsequent experience of breast cancer will be determined by an intensive follow-up through the cancer registration system during the next few years

In much less sophisticated conditions, Dr J HIGGINSON (South Africa) has conducted surveys of cancer incidence among the indigenous communities of Africa Here, sample inquiries combined with sociological studies have been needed to fill in the picture which would have been obtained by routine census data in more highly developed countries Much emphasis was placed on the results of necropsy, and Dr Higginson affirmed that cancer of the liver, œsophagus, and sinuses and Kaposi's hæmangiosarcoma are commoner in Bantu males than in United States Whites The Bantu female suffers excessively from cancer of the cervix Cancer of stomach and large bowel are rare in both sexes

Cancer of the Lung

In the United States, Dr H F DORN has conducted a survey of mortality by cause among 290,000 men who in December, 1953, were holding United States Government life-assurance policies Most of them had served in the first world war, and a detailed history of smoking habits was obtained from 83% of them For both respondents and non-respondents, information on the cause of death was collected from death certificates and by special inquiry from the attending physicians The results were expressed in terms of the ratio of the deaths actually observed among smokers of various kinds to the numbers expected at the age-specific death-rates among the non-smoking section of this particular insured group Thus in total mortality this ratio ranged up to 1 58 for those who had smoked only cigarettes—i e , they had a death-rate 58% greater than non-smokers of the same age Regular cigar or pipe smokers, on the other hand, had a ratio of practically 1 That it is rarely too late to change is suggested by the fact that those who had given up regular cigarette smoking had a rate only 31% higher than that of non-smokers As might have been expected from other studies, the highest ratio was for cancer of the lung, among regular cigarette smokers the rate was nearly ten times that for non-smokers These regular smokers also suffered an increased risk of dying from diseases such as bronchitis, pleurisy, and emphysema, peptic ulcer, and cirrhosis of the liver, while their death-rate from coronary-artery disease was 63% higher than the rate for non-smokers Some of these associations, such as cirrhosis and some forms of cardiovascular disorder, may result from the excessive consumption of alcohol to which some heavy smokers are prone, but the close correlation of lung cancer with cigarette smoking cannot be lightly dismissed

---

[1] Stocks, P Annual Report of the British Empire Cancer Campaign, 1957, supplement to part II London, 1958

This latest and striking confirmation of a long series of retrospective and prospective inquiries incriminating cigarette smoking as an ætiological factor in cancer of the lung gave fresh impetus to the discussion of that subject in other sections of the congress

Dr **Richard Doll** reviewed some of the accumulated evidence and discussed its interpretation Berkson[2] has suggested that the association between cigarette smoking and cancer of the lung may be an artefact produced by some peculiarity of the method of investigation Both cigarette smoking and the certification of cause of death are subject to error, and the group observed is inevitably a biased sample of the whole population Again, the association is not confined to cancer of the lung These facts, Berkson asserts, may invalidate the conclusions to which they seem to lead To this Dr Doll retorted that, although not unique, the association of cigarette smoking with death is far closer for lung cancer than for any other cause, and that the quantitative relationship between cigarette consumption and lung-cancer death risk is remarkably constant in many studies

That incipient cancer would stimulate the desire to smoke was unlikely, Dr Doll thought, for smoking often begins forty years before any symptoms and signs of the disease become manifest Nor does there seem to be any good reason to believe that such a close association is due to some third agent which is common to both cigarette smoking and the risk of lung cancer Hereditary tendencies and air pollution may be relevant factors, but their presence is insufficient to explain the increasing incidence of the disease in cigarette smokers of the present generation Experience with industrial and other forms of exposure to lung irritants suggests that cigarette smoking has a similar effect, in that it increases the risk of lung cancer without decreasing the risk of cancer of other sites

The weakest points in the cigarette theory of lung-cancer causation are the similarity in the experience of those who describe themselves as inhalers and those who deny inhaling, and the disparities between the lung-cancer death-rates in countries with similar cigarette consumption There may be physical explanations for the surprisingly favourable experience of inhalers The irregularity of the national rates may derive from differences—e g , in the amount of the cigarette actually smoked—which are now being investigated in several countries

Against these imperfections in the crude epidemiological data must be put the striking contribution to geographic pathology described by Prof **Leiv Kreyberg** in a congress lecture He pointed out that primary epithelial lung tumours do not constitute oncological entities although, in both mortality and morbidity statistics, they are treated as such Inevitably this leads to an obscuring of the pattern of epidemic behaviour which can be clarified only by more detailed study of the histological character of the tumours themselves A careful review of some 1000 cases suggested that lung cancers could be divided into two groups on the basis of reasonably objective criteria Group-I tumours included squamous-cell, large-cell, and oat-cell carcinoma, group II comprised adenocarcinoma, bronchiolar-cell carcinoma, benign and malignant adenoma, and salivary-gland tumours The importance of this distinction lies in the demonstration that group-I tumours, which increase in frequency with age, are related to exposure to irritants of all kinds including cigarette smoke, whereas the group-II tumours may occur even in young adults and with equal frequency in males and females, in different occupations and in town and country Because of the constancy in the incidence of this second group of tumours, the ratio of group-I to group-II tumours in any unselected series of lung neoplasm may be very useful in epidemiological studies As Professor Kreyberg showed, the ratio goes in step with the increasing incidence of lung cancer associated with cigarette consumption and may thus act as an index of changing circumstances in the natural history of the disease He also showed that this classification could be made quite objectively without reference to the patient's smoking or other history, and if standardisation of his procedures on an international scale can be achieved, there will be a bright prospect for epidemiological studies based on comparisons of such ratios even in countries without effective registration systems

When similar pathological distinctions were looked for in the lungs of guineapigs and rats which had been injected intrapleurally with chromite ore roast, Dr **W C Hueper** (U S A) reported, squamous-cell carcinoma, adenocarcinoma, and other malignant and premalignant types of change were found The carcinogenic properties of metals and minerals such as chromium, nickel iron oxide, radioactive metals, arsenic, and asbestos have been most strongly suggested, however, by the epidemiological evidence of excessive mortality from lung cancer among men exposed to such dusts by their work

These studies of lung-cancer mortality after occupational exposure to dusts again raised the question of air pollution in our industrial cities as a possible cause of the rising incidence in this country, and Mr **R E Waller** (Britain) reviewed the evidence for such an effect He pointed to Stocks' finding of higher lung-cancer death-rate in large towns than in rural districts, but then went on to suggest that the mortality experience of successive cohorts of men in town and country was quite consistent with the gradual spread, during this century, of the habit of cigarette smoking outwards from the main population centres

The mounting evidence against cigarette smoking has inevitably turned attention to the possibility of reducing the associated risk of lung cancer Dr **E L Wynder** (U S A) described a series of experiments designed to identify the carcinogenic elements in cigarette smoke and the critical features of their production which might be modified to reduce their noxious action Better filtration of tobaccos chosen for their low tar content is one alternative, removal of the precursors of the carcinogens produced by pyrolysis is another He illustrated some hopeful studies on the results of variation in burning process which hold out the prospect of a worth-while modification of the burning qualities of cigarettes As long as cigarette smoke remains for most people an incurable addiction, such modifications are the only hope of mitigating the current epidemic of lung cancer

---

[2] Berkson, J , *J Amer stat Ass* , 1958, 53, 28

Mammary Cancer

Dr Charles Huggins (U S A) reviewed the hormonal ætiology and treatment of breast tumours in masterly fashion

In a symposium on the clinical management of breast cancer, the consensus of opinion was that radiotherapy judiciously applied offers the greatest chance of improving the results of mastectomy, but in the view of Mr Hedley Atkins (Britain) the extreme radiotherapeutic techniques advocated by McWhirter still needed substantiation by a controlled trial

Dr C D Haagensen (U S A) stressed the importance of selecting treatment to suit the stage of the condition He described his technique of triple biopsy of the primary tumour, the internal mammary glands, and apical axillary glands, on the results of which the decision as to treatment is largely based In early cases thus selected he recommended radical mastectomy

Prof D W Smithers (Britain) reviewed the factors other than treatment which affect the prognosis, laying particular stress on the histological type of the tumour and emphasising the great difficulty in excluding biological factors when attempting to evaluate treatment

Mr R S Handley (Britain) summarised his observations on the importance of spread to the internal mammary glands, especially in tumours affecting the inner half of the breast. In his series of 150 patients submitted to radical mastectomy with intercostal biopsy, who were followed for five years or more, of those with no glandular involvement 84% were alive and well, whereas of the 41 patients with involvement of both sets of nodes only 2 were alive

Dr M. Margottini (Italy) summarised the arguments in favour of extended radical surgery in the treatment of carcinoma of the breast He emphasised that this operation does not increase the number of operable cases, but, in contrast to some other speakers, he thought it might improve results, though it is too early yet to reach conclusions

Dr F Baclesse (France) reported his results in the treatment of carcinoma of the breast by radiotherapy alone Prof S A Kholdin (U S S R) discussed the management of the disease in general, laying particular emphasis on the need to modify treatment according to the extent of spread

Dr A Loufty Aboul-Nasr (Egypt) discussed the treatment of patients with advanced, widespread disease He recommended oophorectomy particularly in such cases occurring before the menopause, reporting that in his experience this produced a remission in 40% He felt that generally hormone therapy gave better results than chemotherapy

Dr R Luft (Sweden) also recommended oophorectomy for women with advanced carcinoma who were still menstruating or were only one year postmenopausal In his experience, if this produced no remission, then no benefit was likely to follow adrenalectomy In postmenopausal cases it is his practice to prescribe œstrogens, and if this produces a remission the patient is likely to benefit from ablation of the pituitary or adrenals He suggested that hypophysectomy generally produced a longer and more complete remission

It was apparent that adrenalectomy is a much more feasible routine treatment than hypophysectomy, owing to the greater and rarer skill required for the latter operation But implantation of radioactive yttrium into the hypophysis (described by Mr A P M Forrest [Britain]), causing more or less total destruction, may in future be practised at many centres if a more reproducible technique proves effective

As regards the important decision whether abortion is justified in mammary cancer occurring during pregnancy, the general opinion was that this was desirable only during the first trimester, and that the hormonal conditions during the latter stages often antagonised the disease

At this panel meeting a wide range of questions was submitted by the audience The different opinions expressed by the experts emphasised in a dramatic and stimulating way that advanced thought on this subject is now passing through a shifting, formative phase

In experimental mammary carcinogenesis Dr Huggins and Dr Harry Shay (U S A) showed the value of intensive limited carcinogen treatment of rats to produce either dependent mammary neoplasms or latent carcinomas on which hormonal influences could be investigated

Cancer Detection by Cytological Methods

Dr Ruth Graham (U S A) and Prof H C McLaren (Britain) described methods of screening patients for carcinoma of the cervix in a cancer hospital and a general gynæcological clinic respectively The number of patients investigated is impressive—amounting to many thousands—and Professor McLaren was clear that this method is of little value in the detection of invasive cervical cancer (where clinical methods of diagnosis are adequate) but would pick up 4–5 cases per 1000 of "carcinoma in situ" The problem is then how to treat these patients, who should be able to expect a cure Half may be cured by ring biopsy, but the remainder will eventually need hysterectomy and all must be kept under constant cytological investigation

Dr L V Ackerman (U S A) discussed cytological examination of the spectrum after aerosol stimulation of the air passages, and suggested that all men over 40 years of age who are heavy smokers and live in a polluted atmosphere should be screened in this way

Prof J B Duguid (Britain) described his personal change of opinion in regard to the cytological examination of gastric washings for diagnosis of early stomach cancer and emphasised some very important points This is not the kind of work for a small hospital laboratory—it is the work of a specialist The surgeon and the pathologist should be aware of the difficulties, and of the need for an adequate specimen, representing all parts of the stomach mucosa and reaching the laboratory quickly Malignant cells will rarely be present in large numbers, repeated examinations may be necessary, and it will not always be possible to say whether the cells seen are malignant or not

Running through these papers was the knowledge that these examinations are costly and time-consuming It is computed that to screen 6000 persons for cervical carcinoma, 1000 hours at the microscope are required Suggestions for selection of patients for screening tests included omission of those under 30, those who have not borne children, and practising Jewish women, in whom cancer of the cervix is rare A point of controversy concerned the responsibility for the diagnosis Professor McLaren thought that the technicians who do the screening should accept responsibility for diagnosis, while Professor Duguid thought that only a pathologist with a good knowledge of morbid histology should undertake this It seemed clear that the help of technicians is essential for large-scale screening

Ætiology of Cancer of the Bladder

Dr Georgiana Bonser (Britain) described the work leading to the conclusion that 2-naphthylamine was carcinogenic to the bladder of man and the dog by virtue of its conversion to 2-amino-1-naphthol Metabolic studies had revealed the importance of this transformation, and the findings had been confirmed by the technique of bladder implantation

Dr Bonser discussed the extension of this work to the other industrial aromatic amines and hypothetically to other chemical compounds The orthohydroxyamines were of importance in amine carcinogenesis in general

Prof E Boyland (Britain) described two possible ways in which the carcinogenic compounds might be liberated—namely, by the action of glucosiduronidase on glucosiduronidate, and by phosphatase on phosphate—and he discussed the possible action of enzymes on metabolites which have yet to be discovered

Dr W F Melick (U S A) described the incidence of industrial bladder tumours in workmen exposed to *p*-xenylamine Since his original communication further tumours have been found The degree of exposure of workmen was severe, judging from the amount of free xenylamine found in their urine, and the shortest exposure leading to the formation of a tumour was only 131 days Dr Melick indicated that ureteric and pelvic tumours had occurred in his series

Dr J L Billiard-Duchesne (France) surveyed the occurrence of benzidine bladder tumours in the workers in the French chemical industry He said that this was in line with the findings in other countries with an established chemical industry He strongly recommended the routine cystoscopy of workmen engaged in hazardous work, and that this be extended to all workpeople who had been in the industry for fifteen to twenty years

Dr J Clemmesen (Denmark) described a statistical investigation of papilloma of the bladder amongst an urban and rural population in Denmark His evidence suggested, although far from conclusively, that there was a connection with tobacco smoking

A number of papers dealt with related topics Prof R Truhaut (France), Dr D B Clayson (Britain), and Mr L Bradshaw (Britain) each described a particular aspect of the fate of an aromatic amine in the animal body These studies showed that orthohydroxyamine conjugates were formed from benzidine and 4-aminodiphenyl Mr Bradshaw showed that the urine of rodents dosed with 3-hydroxy-4-nitrodiphenyl contained more 3-hydroxy-4-aminodiphenyl than did the urine of rodents to which 4-aminodiphenyl had been administered

Dr H R Gutmann (U S A) demonstrated in the case of an orthohydroxyamine derived from 2-acetylaminofluorene that protein binding was possible in simple biochemical systems

Dr R R Brown and Dr J M Price (U S A) showed that patients suffering from cancer of the bladder often metabolised tryptophan to orthohydroxyamine derivatives more readily than normal persons This effect is reversed if vitamin B_6 is administered In view of the suggestive evidence of Boyland and his co-workers that 3-hydroxyanthranilic acid may be carcinogenic, this indicates a possible mechanism by which some spontaneous tumours may arise

Carcinogenesis

Dr I Berenblum (Israel) discussed the possible relation of metabolism of carcinogens to their action and suggested that with the polycyclic hydrocarbons the evidence did not permit of any conclusion as to whether the carcinogen or its metabolite was decisive in carcinogenesis He mentioned the possibility that hydroxylation followed by methylation preceded carcinogenesis, but again he said he could offer no evidence With the amines, however, there was evidence that 2-amino-1-naphthol was carcinogenic, whereas 2-naphthylamine was not Protein binding and the protein deletion hypothesis were too unspecific to lead to a satisfactory theory The metabolism of urethane suggested that changes in the nucleic acid induced by this chemical or its metabolites might be connected with carcinogenesis, but the evidence was not complete In conclusion Dr Berenblum thought that perhaps we were wrong in looking for a unifying theory of cancer, and that the disease might have multiple origins

The use of a new experimental species in cancer research was described by Dr H E Pogosianz (U S S R) and her collaborators, who have investigated the Steppe-lemming and found it to be similar to the mouse Mouse sarcoma 180 has been transplanted into this species without the use of adjuncts to depress immunogenic resistance This animal is resistant to ectromelia

Dr J G Fortner (U S A) has investigated the effects of implanting pellets into the gallbladder of cats Pellets containing the known carcinogen methyl cholanthrene induced tumours, whereas pellets containing bile extracts or gallstones were negative This worker also found a wide variety of spontaneous tumours in his colony of Syrian hamsters

The induction of cancer of the stomach in the experimental animal remains a difficult problem Dr S C Skoryna and his colleagues (Canada) have repeated the observation that it may be induced with carcinogen-impregnated threads, while Prof Olav Torgersen (Norway) is continuing an investigation into the effects of heated fat

The main difficulty with the electron distillation theory is that, however precise the electron density calculations, they must be correlated with imprecise biological data

Dr Ronald Mason (Britain) has used the molecular orbital theory to study the forces operating between the carcinogen and the protein with which it is interacting At present this idea does not seem to be capable of experimental test and its relation to practical carcinogenesis is obscure

The present state of the experimental investigation of protein binding of the hydrocarbons was described by Dr Charles Heidelberger (U S A), who believes that this is correlated with carcinogenic activity He was unable to suggest any evidence as to the nature of the essential enzymes which were "deleted" as a result of protein binding Dr D L Woodhouse (Britain) has been unable to obtain convincing evidence that protein binding is in any way specific—possibly because of experimental difficulties in the system he studied

Immunology and Immunogenetics

Dr E Weiler (U S A) showed that organ-specific antigens are lost from rat liver and hamster kidneys in the process of carcinogenesis By a series of ingenious isotopic techniques combined with standard immunological methods, he found that normal hamster kidney grown in vitro also loses these organ-specific proteins after a short time His work directly supports that of Prof H N Green (Britain) on the immunological deletion of organ-specific antigens in carcinogenesis But Sir Macfarlane Burnet (Australia) in an impartial survey of the biological aspects of cancer concluded that these stimulating ideas needed more critical experimental backing

Dr Ilse Lasnitzki (Britain) illustrated how organ culture techniques can be applied to fundamental biological problems, and emphasised the advantage of these methods over the in-vitro cultivation of single cell species

The evergreen topic of virus involvement in cancer ætiology attracted much discussion, but in comparison with previous times interest in this field of research seems to have diminished In particular no-one pursued the idea that human mammary cancer was of viral origin Sir Macfarlane Burnet concluded that viruses have no significant role in human cancer except for possibly some part in the induction of leukæmia

Hormones in Genesis of Cancer

Prof O Muhlbock (Holland) presented evidence substantiating the idea that hyperhormonal pituitary stimulation can lead to cancer of the target organ This aspect has been broadened by the Dutch workers' demonstration, described by Dr L M Boot, that breast carcinoma can be induced in milk-agent-free mice by the repeated subcutaneous implantation of pituitaries from animals of the same strain

Ovarian carcinogenesis was discussed by several workers, among whom Prof A Lipschutz (Chile) made a notable contribution He suggested that the origin of so-called granulosa cell tumours of the ovary might in some cases be in the ovarian stroma, and he described the histological changes occurring in the evolution of these tumours produced by intrasplenic grafting or subtotal castration Apparently the sequence of changes in the two methods is similar, but in the ovarian fragments in situ the malignant transformation does not usually proceed beyond the stage of luteoma during the lifetime of the animal

Induction of ovarian carcinogenesis by a newer method was described by Dr J Marchant (Britain), who showed that in the ovaries of mice, treated for a limited time with 9 10 dimethyl 1 2 benzanthracene, transplanted to the ovarian capsules of untreated animals, tumours still occur to the same extent and in much the same time Normal ovaries, however, do not develop into tumours when transplanted into mice which have previously been treated with the carcinogen

Dr F Bielschowsky (New Zealand) described the evolution of autonomous growth in thyroid neoplasms and correlated this with their dependence on secretion of thyroid-stimulating hormone (T S H) by the intact pituitary

Dr S H Wollman (U S A) showed that the ability of individual thyroid tumours to take up iodine could be a measure of their malignancy—although in some instances, paradoxically, the hypersecretion of the tumour completely inhibits T S H production, illustrating the autonomous nature of the particular growth

Dr J Furth (U S A) described the multiple potentialities of tumour production in the irradiated pituitary and showed how functional neoplasms of different types could be obtained This approach to carcinogenesis obviously holds out hope of considerable advances in knowledge of the normal interrelations of the endocrine system

Chemotherapy of Cancer

Dr C C Stock (U S A) reviewed the problems in setting up an efficient screening programme for thousands of compounds The ideal of testing every compound against every test system being impracticable, the quick type of microbiological investigation is probably the best preliminary test, followed, in the case of promising materials, by more thorough testing against a range of animal tumours and human tumour implants This secondary investigation should include tests against a solid tumour, an ascites tumour, and a leukæmia, with human tumours carried by implantation as preferable additional systems It was generally thought best to err on the side of using test tumours very sensitive to drug action, leaving tests on the spontaneous, and usually more resistant, tumours to later stages of the programme

Prof T Yoshida (Japan) emphasised that laboratory tumours rarely metastasised, so that this important facet of neoplasia in man is in danger of being insufficiently attacked His group have therefore produced strains of ascites tumours, especially hepatomas, where invasion of the blood-stream by tumour cells can be seen as early as twenty-four hours after implantation

Prof A Haddow (Britain) suggested that prevention by chemotherapy might be easier to attain than outright cure, and he described a series of compounds which, in the laboratory, would totally inhibit the growth of implants of Walker rat carcinoma Another series of compounds related to the alkylating agents (in the development of which the Chester Beatty Institute have played a large part) were much less toxic to the host than those presently used But however bright this experimental picture appears, Dr Haddow's healthy scepticism led him to predict that the future of chemotherapy lay in fundamental studies of the normal and neoplastic cell rather than extension of cytotoxic or cytostatic principles

Dr G Mathé (France) discussed the treatment of neoplasms of the hæmatopoietic system with substituted di-ethylene-imine-benzoquinones, and the subsequent discussion ranged from the problems of drug resistance to the question whether in health man has inherent defence mechanisms against malignancy

Dr S Farber (U S A) gave a comprehensive review of chemotherapeutic agents whose mode of action is that of an antimetabolite, an antibiotic, or an anti-enzyme, with particular emphasis on actinomycins C and D and the anti-folic-acid drugs After emphasising that tumour retrogression by chemotherapy alone, while uncommon, was not unknown, he suggested that the day would come when every malignant condition would respond to therapy by compounds completely non-toxic to the host, and that even active immunisation against all types of cancer would finally be achieved

Prof L F **Larionov** (U S S R) described the experience of some Russian clinics with various types of alkylating agents, and indicated that better effects were to be expected by combining the active alkylating centre through a natural aminoacid to another carrier such as a vitamin or peptide, so lessening host reactions Of great interest was his evidence that certain types of malignancy, notably Hodgkin's disease, could be cured by alkylating agents alone provided that the dosage was properly controlled, pushed to the limit of the patient's tolerance, and continued by maintenance and, finally, prophylactic therapy

CHEST DISEASES

The triennial discussions on tuberculosis in the Commonwealth countries, which the National Association for the Prevention of Tuberculosis has fostered in the past fifteen years, have been steadily broadened both clinically and geographically This year's conference, held in London on July 1–4, was combined with the annual conference of the British Tuberculosis Association and was attended by delegates from countries and dependencies in all five continents

Anti-tuberculosis Campaign

Dr **Johannes Holm**, chief of the Tuberculosis Section of the World Health Organisation, epitomised his outlook in the declaration "Tuberculosis is a public-health problem as long as there is a risk of any individual in the community contracting the disease" Prevalence of *demonstrably infectious pulmonary tuberculosis* varies from a rate of 20 cases per 1000 adults in parts of Africa to 1 per 1000 in Denmark More than half the children aged 15 years in the Somalilands, Ethiopia, and West Pakistan show evidence of infection Indian surveys have surprisingly shown that tuberculosis there is as prevalent in village communities as in those of urban areas Mass vaccination with B C G, because it is effective and easy to arrange, is at present more widely applied in the world than is diagnosis and chemotherapy, whose practical application among scattered poor communities presents immense difficulties

In contrast to current trends in this country, several speakers made a plea for more hospital beds for tuberculosis, and more trained specialist staff, for tropical countries The dangers of giving isoniazid alone, and the paramount importance of effective chemotherapy were emphasised Relapses after even long-continued drug treatment was discontinued, and the emergence of resistant bacilli after too little chemotherapy, showed that tuberculosis treatment should still be a specialised enterprise

Infection in Laboratories

A series of papers described the hazard of tuberculous infection among laboratory workers from sputum containers, culture bottles, and laboratory animals The recommended prophylactic measures included air hygiene, personal hygiene, technique cleanliness, work supervision, and health supervision especially of junior staff, along with tuberculin tests and B C G vaccination on entry to the service and periodic chest X-ray examination Although this subject has produced a growing literature only in the past few years, it was in fact mentioned by Robert Willan [1] in his report on the diseases of London for the year 1800, in which he listed "bricklayers' labourers, laboratory men, coalheavers and chimney sweepers" as specially liable to "obstinate pulmonic diseases terminating in consumption".

Surgery for Pulmonary Tuberculosis

The place of surgery in treating pulmonary tuberculosis was debated with great vigour round the lessons to be drawn from the report,[2] which we have lately reviewed,[3] of a widespread study of the results of thoracic surgery in the United Kingdom during 1953–54

It was made clear that a historical study of this kind has only very limited application to current circumstances The therapeutic compass today is pointing away from surgery in tuberculosis In 1957–58 in England and Wales 1168 collapse operations and 3380 resections were performed, compared with 4207 collapses and 3923 resections in a similar period four years ago Nevertheless it was significant to hear a senior hospital physician declare "I am not convinced now that chemotherapy is so dependable that consideration of surgical intervention is *no longer important*" Results after tuberculous lung surgery depend on the extent, destructiveness, and drug resistance of the disease, and the age and sex of the patient Adequate chemotherapy, says the report, is the most important factor in surgical success Women under 40 with limited unilateral lesions which were drug-sensitive showed the best results Yet these very criteria cannot fail to prompt the query, "Was your operation really necessary?" In surgery of all kinds, the best technical results are achieved in cases where operative interference is least necessary While the physician is compelled to turn to the surgeon for help with the patient whose cavity persists, excreting resistant bacilli, the surgeon will not welcome a patient on whom he must operate without benefit of effective chemotherapeutic cover It appears that in such cases modern thoracoplasty gives better results than resection in this country United States practice is different There collapse operations are being abandoned in favour of excisional surgery, but according to Dr J **Maxwell Chamberlain** (Columbia University) it is American practice to operate most readily on early cases, before chemotherapy has been long established—partly, it appears, because hospital stay is thereby shortened, and because there are pension-computing advantages to ex-Service patients who can show thoracotomy scars

Radiography

Mass radiography of the "hazard groups" in the community was confirmed as of value in eliminating sources of infection Household contacts, middle-aged and older men, lodging-house residents, tuberculin-positive adolescents, and unvaccinated immigrants who have been exposed to high infection risks here give the highest yield *There are still many adults in this country who have never been X-rayed*

On possible risks from diagnostic radiography it was reassuring to hear from Dr J F **Loutit** that the chance of serious genetic damage was negligible when well-maintained modern apparatus is used, with strict attention to technique designed to avoid radiation to organs containing *germinal* epithelium Frequently repeated exposure to diagnostic radiology *might* produce a summation risk of leukæmia, but even this danger was considerably reduced when only part of the body's bone-marrow was exposed to radiation On the whole it seemed that any very small risk there might be of leukæmia following diagnostic X-ray examination is enormously outweighed by the chances of early X-ray diagnosis of lung disease

Atmospheric Pollution

Three centuries and more have passed since our King James I's[4] tirade and John Evelyn's[5] lament tried to influence public opinion against the pathological effects of "that hellish and dismall cloud of sea coale so universally mixed with the otherwise wholsome and excellent aer, that her inhabitants breathe nothing but an impure and thick mist corrupting the lungs so that catharrs, phthisicks, coughs and consumptions rage more in this one city than in the whole earth besides"

Much the same sort of complaint was made by Dr P J **Lawther** and others at the conference, when more evidence—chemical, physical, meteorological, and statistical—was adduced to correlate chronic bronchitis and lung cancer with particulate and gaseous pollution of the ambient air and with tobacco pollution of the bronchial mucosa Lawther defines three grades of atmospheric pollution

(1) An "acute" form, occurring when smoke is trapped under an immobile cold anticyclone air layer, also labelled "smog" This is an uncommon, freak, climatic event, fraught with fatal danger to old people and cardiorespiratory cripples

(2) "Subacute pollution," comprising the more frequent episodes of winter fog of short duration which spell exacerbation and relapse for the chronic bronchitic

(3) "Chronic pollution," Lawther's term for the endemic winter air contamination of English industrial towns The active principles of this pollution are mainly suspended carbon of various types, tars, and sulphuric-acid particles These are suspected to be the factors inducing recurrent bronchitis and lung cancer

This simple classification receives support in the analysis by Gore and Shaddick[6] of increased mortality in London during periods of measured varying atmospheric pollution, and in the second[7] of Reid's Milroy lectures

Cigarette Smoking

Prof **Alexander Kennedy** explained convincingly that only a sudden, determined, and complete wrench—if necessary by hypnosis—could enable the heavy cigarette smoker to give up his addiction Attempts at gradual reduction by self-rationing are less likely to succeed Supporting sympathy and restraint by relatives and friends are necessary

Tuberculosis and Sarcoidosis

One of the most exciting discussions dealt with the relationship between tuberculosis and sarcoidosis Dr J G **Scadding** cautiously defined sarcoidosis only in terms of its characteristic morbid histology—epithelioid-cell nodules without necrosis or round-cell infiltration and, in chronic lesions, with hyaline deposits Sarcoidosis could be a phase of tuberculous disease with weak tuberculin allergy Typical sarcoidosis has been identified in a patient who a few years earlier had tuberculous cervical glands from which human-type bacilli had been recovered Most cases of sarcoidosis show no response to ordinary antituberculous chemotherapy unless corticosterone is added In some, frank tuberculosis appears later, and with it is acquired tuberculin sensitivity with subsidence of the sarcoid lesions During cortisone therapy in sarcoidosis, it is common to witness the emergence of tuberculin sensitivity Though no bacilli have been demonstrated in sarcoid lesions, mycolic-acid residues characteristic of tubercle-bacillus breakdown products have been identified On ætiology Dr Scadding felt compelled to ascribe the majority of cases he has seen in this country to tuberculosis, but he would not exclude other possible causes such as beryllium, and in other countries there may be yet other excitants

It is interesting to compare this conclusion with one expressed twenty-eight years ago by Sir Archibald Gray,[8] who, in discussing subcutaneous sarcoid, is reported as saying he considered that these lesions represented a group of reactions rather than a specific disease and that some of the lesions might be tuberculous Interesting in this connection, too, are the lung nodules in Caplan's syndrome—the sharply defined round lesions found in the lungs of rheumatic coalminers, where no evidence of active tuberculosis and no bacilli are found, yet characteristic concentric tidal deposits of macrophages and coal-dust are seen among dense fibrous strands Here, too, mycolic-acid residues are demonstrable

An alternative ætiology for sarcoidosis was postulated by Dr **Harold L Israel** (Pennsylvania), who defined the condition as "a prototype of granulomatous reaction" increasingly prevalent in the United States, and rarely associated with erythema nodosum It is more than ten times as common in Negroes (especially young women) as in Whites The view formerly held in America that sarcoidosis is an atypical tuberculosis has now apparently been abandoned in favour of a notion that it is a specific allergic hypersensitivity reaction to an "inert" substance—possibly pine-tree pollen In supporting this hypothesis Dr Israel averred that most American patients with sarcoidosis came from pine-forest areas, and that pine pollen contains lipid and has acid-fast staining properties, and when injected into animals produces granulomas—though not in the lungs

---

At the annual dinner of the British Tuberculosis Association on July 3, Dr **Owen Clarke**, the hon secretary, said that, whereas formerly the word "tuberculosis" carried a stigma for the patient, today it carries a stigma for the doctor Many chest physicians are almost ashamed that they handle cases of pulmonary tuberculosis, and seek to emphasise the wide range of other diseases in which they are masters What a tragedy of perverted thinking! For the duty of a good doctor is to restore his patient to full economic independence and social stability, and there is no branch of medicine in this country which teaches this principle so well as does tuberculosis work The chest physician is at the head of a team which is closely concerned with the treatment of disease, the social complications which may arise from it, and the public-health problems involved Does any other consultant really concern himself personally with all these aspects of medicine? On the clinical side, the Association's members have time to expand their work into other branches of chest disease, and their special training and experience makes them well fitted to do so But let them beware lest in trying to increase their importance they succeed only in diluting their special ability and lose their real understanding of good medicine Our own specialty, said Dr Clarke, is surely one of the most fascinating and progressive in medicine, and should continue to demonstrate that the treatment of sick people demands more than an interpretation of scientific jargon and even today is a human art involving the whole structure of the man's securities

British Medical Association

ANNUAL REPRESENTATIVE MEETING

THIS year's Annual Representative Meeting of the British Medical Association, which ended at Birmingham on Monday, was not one of the liveliest of recent years. The announcement of the rejection of the claim for a further interim increase in remuneration was received with apparent inertia by an audience whose reactions seemed to have been deadened by past experiences.

The Association met under the presidency of Prof. A. P. THOMSON (Birmingham), and the Annual Representative Meeting was held in the great hall of the university at Edgbaston, with Dr. A. BEAUCHAMP (Birmingham) in the chair.

The Duke of Edinburgh had graciously consented to accept nomination for President, and the Association "honoured itself by electing His Royal Highness as President for 1959–60", standing orders being altered for the purpose.

NO INTERIM AWARD

Dr. SOLOMON WAND, chairman of council, told representatives that the Minister of Health had refused a further interim adjustment which had been requested because the Royal Commission on Doctors' and Dentists' Remuneration had not reported by Easter, as had been hoped. An application was made because of the previous Minister of Health's undertaking when the Commission was set up. Dr. Wand and others met Mr. Walker-Smith on June 17. "This letter was placed in my hand yesterday afternoon at 3 o'clock," commented Dr. Wand, holding up the Minister's reply on July 10. The letter recalled that when the medical profession's delegation came to the Ministry there was a $2^3/_4$-hour discussion. The Minister then gave, in what he described as "a highly summarised form", the reasons why he was not able to agree to an immediate further adjustment.

"You pointed out that my predecessor had undertaken that a claim could be considered if the Royal Commission had not reported by Easter 1958. (You will, of course, remember that my predecessor's letter of June 6, 1957, in which he gave this undertaking, concluded with the phrase 'But you will, I know, understand that it is impossible for me to commit myself in any way at this stage, when neither we nor you can have any idea what might happen in the interim or what such a claim might amount to.')

"The reasons why I am unable to agree that the circumstances warrant a further interim increase at the present time are broadly two-fold. In the first place, although the Royal Commission are not yet ready to report, they are pressing ahead with all speed and, assuming that their report is not unduly delayed, a further increase would run the risk of prejudicing their work. Secondly, the economic situation of the country at the present time must be taken into account. Circumstances since April and May, 1957, to date have not changed so greatly as to justify an increase. Moreover, no other people remunerated from the public purse who received a pay increase of 5% in April and May, 1957, have yet received any further award. A further award to the doctors might well lead to claims for increases in remuneration of an inflationary nature from others and it remains just as important as ever to secure stability in wages and salaries.

"It is of course open to the Association to make further representations at any time but what I have said in this letter represents the view I am bound to take at present."

Dr. Wand remarked that it had taken a long time since June 17 to say 'No'. Would an increase prejudice the Royal Commission? A new grade of registrar had been determined unilaterally by the Minister: did that prejudice the Royal Commission any less than an interim adjustment? How did the Minister know that the Royal Commission would be prejudiced by such a change? Dr. Wand had offered to write to the chairman of the Royal Commission to find out whether such an adjustment would prejudice the Commission.

Of the economic situation Dr. Wand declared: "Whenever we go the economic situation is wrong." But in any event what was the relevance of the economic situation? Had any other section of the community received only 5% increase since 1951? As to the Minister's statement that he would be pleased to receive further representations, Dr. Wand said: "We have heard that one before, but we are going back after all." He suggested that the representative body should have time to ponder on this letter and that discussion be deferred until later in the meeting.

After ten years of the National Health Service, Dr. Wand thought that the most important feature was the wonderful service that was being given to the public. The public had had wonderful value for its money. That was due to the devotion, in spite of many frustrations and disappointments, of those engaged in the practice of medicine and associated professions and callings. After ten years doctors could also say that their relationship with Government officers had been good, consistently good. When it came to the realms of higher policy, could the same be said about relations with the Government? (Cries of "no".) Dr. Wand said that he was not only thinking of remuneration when he said that the profession must be alive to the danger of unilateral decision. The unilateral decision, carried on indefinitely, would lead to control.

REVIEWING THE MEDICAL SERVICES

The representative body authorised the council, in consultation with the Royal Colleges, the Scottish Royal Medical Corporations, the College of General Practitioners, and the Society of Medical Officers of Health, to determine the size and the precise composition and terms of reference of the committee to review the medical services, and to appoint the chairman of the committee.

Dr. J. S. ROSS (East Herts) thought that doctors could not have the type of health service they wanted until it was known what form of service the majority of them would support. His motion to this effect was referred to council.

Dr. B. BURNS (Sheffield) was for saying what was known to be true, even if it was unpopular. This revelation turned out to be that the frustration of family doctors arose from two basic causes—the terms of service inseparable from capitation-fee remuneration, and the abuse of the "free" service by certain patients. A relentless minority of patients were cadgers and whiners who trifled with doctors' time and leisure. If patients wanted doctors' time, they must be prepared to have a value placed upon it. They must be prepared to pay for it. The capitation fee brought out the worst in the doctor, and the "free" system brought out the worst in the patient. But Dr. J. S. NOBLE (Morpeth) felt ashamed that the representative body was being asked to blame patients. "Doctors are responsible for running their practices," he said. "Responsible doctors produce respect."

A younger practitioner's view was put by Dr W P Lambie (Sheffield) The great majority of young practitioners, often insidiously prompted by those in high office to whom they looked for help and guidance, were clamouring for a full-time salaried service "We cannot continue as at present and the only real alternative to the capitation-fee remuneration is a fee per item of service" It would wipe out the present frustration and discontents, particularly if patients paid a proportion of the cost of the items at the time

PARKING PROBLEMS

"It is not impossible that if some solution is not found for doctors' parking problems, people living in the centre of big cities may not be able to obtain a National Health Service practitioner to look after them" Dr Wand's warning was referred to by Dr I M Jones, chairman of the private practice committee, who said it was quite impossible for a doctor to deal properly with a patient if he was all the time wondering whether his car would be there when he came out or whether he would be apprehended The Ministry of Health had offered to join a deputation to the Ministry of Transport Though the Minister of Transport at first refused to see the Association at all, he later agreed to see its representatives immediately after the St Marylebone parking-meter inquiry report had been issued, and after he had taken his decision on that report He had, however, indicated that no extension of parking meters would be made until the Marylebone scheme had had a full trial and until after he had had discussions with the Association

COORDINATION OF THE PROFESSION

Intraprofessional relations and the coordination of the profession, in the light of what was described as "the coming medicopolitical storm", loomed large in the minds of representatives They approved a resolution, moved by Dr J G M Hamilton (Edinburgh), instructing council to consider "as a matter of urgency" specific arrangements necessary to achieve the "pressing need to improve intraprofessional relationships and solidarity"

Introducing the report of the committee on professional coordination, Dr Wand described coordination as something which proceeded by evolution rather than by edict and dictate "We are a democratic institution in a profession where there are many democratic institutions A year ago there were dark clouds in the sky so far as medical unity was concerned It is my belief that those clouds are dispersing" He referred particularly to the setting-up of the review committee

A motion from Lincoln welcomed any action which would promote unity on matters affecting the general welfare of the profession Dr A. M Maiden explained that it was intended that every avenue of approach to the non-politically-minded practitioner in the periphery should be explored

Mr A Lawrence Abel (Marylebone) said it was clear that some action must be taken by the Association to promote unity "Those of us who are not perhaps quite anæsthetised by the Royal Commission will wake up to the fact that we must have every member of the profession in contact with every other," he declared Here was a great chance for the Association to carry out rehabilitation, to make sure that those young men aged 65 who had retired from the service on July 5 were allowed to wear out and not to rust out "I have estimated that if 20 of these young men were employed and provided with a morning coat and top hat, and given travelling expenses, they could visit every doctor in the country who does not attend a B M A meeting—and that is quite a fair proportion" Dr Wand invited any doctor to write to the secretary with positive suggestions

TELEVISION PROGRAMMES

Dr G S R Little (Greenwich and Deptford) declared "I do not think we did good by suggesting that the *Your Life in Their Hands* programmes were a cheap form of entertainment In the main, as many of you must know, they were very good and they did not produce any adverse reactions At least we did not have evidence that they did" He warned the meeting that the public were apt to look on the profession with disfavour "when we batten down and blow cold over things of this nature"

Dr Wand owned that "we may have to review our ethical approach to these developments, which are bound to take place and are taking place in other parts of the world, particularly in the North Americas"

Dr Doris Odlum (Bournemouth) felt strongly that the new medium was a tremendous power for good or evil It quite obviously appealed to the public as a means of education and a source of information There should be such an active relationship with the B B C that the Association could go to them and say they thought a particular programme would be of great value "I hope that we shall not be so conservative as to give the impression that we are hostile or trying to put back the clock."

Harrow withdrew a motion calling on the B B C to consult with the B M A before televising or broadcasting programmes "which are liable artificially to increase the work of doctors and cause anxiety in the population at large"

CANCER EDUCATION

East Yorkshire asked the representative body to deplore the use of television for the purposes of cancer education Dr K W Beetham said the small number of active cancer educators concentrated on the 30% of neoplasms, that could be cured and ignored the lethal neoplasms which were 70% this was not education "If we are not in a position to tell all the facts, then quite clearly our profession should not tell any of the facts," Dr Beetham declared Now 8 million people had had thirty minutes' intensive cancer education from the Christie Hospital, Manchester Some thousands, perhaps hundreds of thousands, might for some time have a mild cancer phobia and some might be more permanently affected

Dr G Cormack (Newcastle upon Tyne), however, had no doubt that education, by and large, was a good thing Why should one oppose the public education of the people on a matter of extreme importance to health? Family doctors were always deploring the late arrival of patients with cancers which could be cured He suggested that the B B C and Independent Television contractors should not only educate about cancer but discourage cancer neurosis at the same time The East Yorkshire motion was defeated

SPENS A CASE FOR THE SCOTTISH COURTS?

The contractual validity of the Spens reports may after all be tested in the law-courts Dr Wand recalled that a resolution of the Conference of Local Medical Committees in June last year caused the council of the Association to explore the possible difference between Scots and English law in relation to this The opinion of Scottish counsel had been taken "The Association has been advised that in Scotland there exists a procedure known as a 'special case' which is particularly apt to raise the question which we wish to have decided by the courts It differs from the usual type of contentious litigation in that the parties amicably agree to present their differing views of the position to the Court for objective decision"

In order to raise a special case it was necessary, in the first place, to have the consent of the Secretary of State for Scotland, as the Minister responsible for the National Health Service in that country, thereafter it was necessary for the Association and the Secretary of State to agree upon a statement of facts and a question or questions of law to be submitted to the court "Both the statement of facts and the questions of law we propose will be so framed as to ask the court to determine whether our view or that of the Government regarding the obligations implicit in the acceptance of the Spens report and the Danckwerts adjudication is correct"

The Minister of Health and the chairman of the Royal Commission had been informed of the Association's decision to seek the agreement of the Secretary of State to the presentation of a case, and the matter had been laid before the Secretary of State

ANONYMITY

Dr C P WALLACE (Guildford) said the Association still intimidated and prevented learned members of the profession from giving information to the public "I can see nothing unethical, immoral, or improper if Mr Lawrence Abel—so well known and highly respected in the representative body—were to address the public on cancer," he continued, "yet, according to the ethical rules of the Association, that would be out of order"

The new chairman of the central ethical committee, Dr S NOY SCOTT, announced that the committee at its next meeting was, at his request, to reconsider anonymity on television

HOSPITAL STAFFING

Mr T HOLMES SELLORS, chairman of the Central Consultants and Specialists Committee, told the meeting of an estimate that there were between 100 and 110 senior registrars in each of the specialties of general medicine and general surgery who, being time-expired, now constituted a group of people who could not be employed although fully equipped in nearly every case for consultant work The Ministry had persistently refused to accept the principle, laid down in the Strachan report, that there should be a review to decide whether hospitals were adequately staffed Instead the Minister had imposed his own attempted solution—the creation of a special type of post to be determined by the regional hospital boards where they felt there was a vacancy for a man doing such advanced work and who could not find a suitable appointment in it "The Central Consultants and Specialists Committee and the Joint Committee have rejected that idea completely as being mere stalling for political expediency," declared Mr Holmes Sellors "The only suggestion of the Ministry which has been accepted as providing a loophole to continue negotiations is the formation of a working party which has as its terms of reference 'to study the whole of hospital staffing'"

The management side of Whitley Committee B had agreed to consider cases of S H M O s doing consultant work Over 10,000 letters had been sent to S H M O s, nearly 1000 replies had been received, of which 500 had been selected as suitable cases to place before the management side for discussion "There is, however, the disconcerting feature that it appears the management side had no idea that the problem was so extensive, and they have quickly reverted to their original terms—that they would look at such cases and see what the nature and size of the problem was, but would not commit themselves any further as to what they would do with them"

Dr C VIPONT BROWN (Manchester) spoke of an aspect of the problem of hospital staffing which was of particular concern to general practitioners Outpatient departments should be regarded as consultative clinics, but in many cases the patients were not seen by consultants The fact that other members of hospital staffs were doing work of consultant status emphasised the need for the creation of more consultant posts

Dr N K SHINTON (Birmingham) proposed a motion deploring the decision of the Minister of Health to create designated senior registrar posts before the recommendation of the working party had been made

Mr H H LANGSTON (Winchester) asked whether the junior hospital staffs group council would be prepared to advise members in no circumstances to apply for these posts Mr R BREARLEY, chairman of the group council, said that he would be prepared to advise such a course of action, and he believed his executive committee would endorse it Mr LAWRENCE ABEL moved an addendum instructing council to refuse advertisements for these posts This was accepted as a reference to council, and the original motion was carried

Also carried was a motion from Birmingham urging speedy action "so that S H M O s whose level of work and responsibility in their present post can be shown to be of consultant standard may be paid as consultants"

DISTINCTION AWARDS

Dr WALLACE, advocating the publication of merit awards, thought that the council seemed unaware that the present method of distinction awards was unacceptable to the profession and contrary to public policy, and he did not feel that the Central Consultants and Specialists Committee could approach the matter with that lack of bias which it demanded On the other hand Scotland, according to Dr A SMITH (Lanarkshire), was well satisfied that the system operated satisfactorily and that publicity would be very wrong

Dr H GLYN JONES (Bromley) thought that if there were within the State service people of such ability that they merited very special awards, they should be known to general practitioners, the people who would refer cases to those consultants

Dr J C KNOX (Tyneside) claimed that the Central Consultants and Specialists Committee did not know what the consultants wanted The consultants in his region felt quite as strongly as the general practitioners about this secrecy His division believed that when the profession had been hesitating whether to enter the Health Service in 1948, information had been divulged by the Minister about who would be getting the merit awards and that had influenced the committee to lead the profession into the service Mr J R NICHOLSON-LAILEY (West Somerset) said it would be grossly unfair to pillory the consultant who had not a merit award The general practitioner knew far better than any merit-award committee who was a good consultant

The debate was cut short by a motion to put the question Mr Holmes Sellors said it was early realised that publication was absolutely impracticable, and he pointed out that consultants in the periphery were able to express their views Dr Wallace held that it was impossible to imagine that it was in the public interest that public money should be dispensed at the instance of a secret committee to secret people He suggested that a secret ballot of consultants and specialists would overwhelmingly throw out the system

After a count, the meeting supported Dr Wallace by 96 votes to 91

NATIONAL MAJOR CASUALTIES SERVICE

Mid-Cheshire asked the meeting to state that it was "not satisfied with the complacency of the council regarding the national major casualties services" Dr W N Leak said "Much has been done in recent years to organise rescue work, but apart from the Didcot disaster, where affairs were chaotic, all have occurred in well-populated areas, where help and hospital were readily available It would, I fear, be very different if a disaster occurred—as it inevitably will in time—in a rural area far from hospital help In such conditions careful planning beforehand may save many lives, but of this planning general practitioners had so far have no indication"

Dr R Smith (S Middlesex) drew attention to the fact that near London airport were the homes of half a million people, who were exposed to the constant menace of disaster from the air The regional hospital board had a plan, but applied to the London airport area it ignored the fact that on the spot in this densely populated area there was already a mobile force of general practitioners —not one of whom would know where to start if he found himself suddenly near the scene of an air disaster The population at risk increased steadily with the development of new housing estates

Dr R. L Meyrick (Lewisham) opposed Mid-Cheshire's view "We had a major disaster last year," he said, "and the arrangements worked with complete satisfaction" The Mid-Cheshire amendment was lost

CONSULTANTS IN TRAINING AND GENERAL PRACTICE

Arrangements for hospital junior medical staff to obtain experience in general practice during their hospital employment should be left to the individual hospital, Marylebone considered Dr E C Warner remarked that it was not only the consultant in training who should have experience in general practice but anybody who would play a part in the medical life in this country

Dr R M S McConaghey (Torquay) thought there was nothing better for harmony in the profession than that each person should have a spell of doing the work of the others

Dr G S R Little (Greenwich and Deptford) did not think it should be left to the individual He was going to specialise, he did not then realise the value of experience in general practice

The Marylebone motion was carried

DEFICIENCIES OF HOSPITAL BUILDINGS

Dr H G H Richards proposed a motion, which was adopted, instructing council to press the Ministry to allocate substantially greater sums to capital development in relation to hospital services "Hospital building in the non-teaching institutions remains the Cinderella of the public service," he complained Out-of-date buildings made for excessive staffs of all types

Dr H Scott-Kerr (Gloucester) recalled that when the National Health Service started the Government of the day promised a full medical service With waiting-lists of three months to two years, the public had been hoodwinked

This point was elaborated by Dr E A Gerrard (Manchester), who said "The position represents nothing less than a public scandal" 4 people were waiting for every teaching-hospital bed in London and 5 for every such bed in the provinces In gynæcology 9 patients were waiting for every bed "In the Middlesex Hospital there are 16 women waiting per bed, in Cardiff 19, in Cambridge 21, and in St Mary's Hospital, Manchester, no less than 26 For a pelvic-floor repair they have to wait from three to four years to come in, at the Middlesex it is two years, in Cardiff three, and in Cambridge three and a half We have had new offices and flats, and particularly new Government offices, and new schools We are of course desperately short of money in this Welfare State, but even so is it fair that little Johnny should attend a diamond-studded school and his mother have to wait three to four years to have her prolapse repair? In my view it is absolutely crazy"

CENTRAL POOL

Dr A B Davies, chairman of the General Medical Services Committee, made a statement about the final settlement ("I really mean supplementary payment, because there is no such thing as a final settlement until our claim has been met," he remarked) For 1956–57 the final settlement was £4,600,000 One reason why it was less than in the previous year was inflation of lists, for the first time total numbers were greater than the total population In addition doctors had received a greater amount of money direct from Government sources Nevertheless, when the total figure was added together, in the past year general practitioners had received the highest total sum on record The timing of the payment had been improved from December in 1956 to June in this year

Bristol demanded a change in the working of the central pool, "which is proving to be unjust and discouraging in its effects" Dr A G Heron described it as a system of merit penalties, general practitioners as a whole could not earn any more, however hard they worked or however much extra work they took on

Dr Wand said that if one had a pool which allowed for an average income for every practitioner, as laid down in Spens, and if, as the Danckwerts award provided, every practitioner coming into the service provided extra money to be divided, then one could not have it both ways On the question of vaccination, he had not heard a speaker point out that general practitioners might have less work to do as a result of such vaccination "With all its faults —and no system is perfect—the pool system has done us well," declared Dr Wand

Bristol's motion was lost

REJECTION OF FURTHER INTERIM AWARD

In a reference to the refusal of the Minister of Health to grant a further interim increase since the Royal Commission had not reported, Dr A M. Read (Portsmouth) commented "We have long since discovered that a gentleman's agreement with a politician is a contradiction in terms" (Applause) Dr R P Hendry (Rugby) remarked that the profession's claim had been given top-priority procrastination treatment

The question was put "That this meeting wholeheartedly supports the council in making continued efforts to secure a further interim increase in remuneration" Dr A Talbot Rogers, deputy chairman "That is passed without a single opposing vote"

SCHEMES FOR WITHDRAWAL

Dr Davies announced that a special subcommittee had been appointed to deal with the matter of schemes for withdrawal from the National Health Service, and an impartial non-medical expert of the highest eminence had been engaged It was hoped to report in good time before the Royal Commission reported

GENERAL-PRACTITIONER BEDS

The meeting passed a motion on the need for more general-practitioner obstetric and medical beds, after rejecting an amendment to delete the reference to medical beds Dr F S Catto (Manchester) attacked Lord Moran's House of Lords suggestion that access should be restricted to certain general practitioners "I believe that every general practitioner ought to have access to these beds," he said "If not, who is to select the general practitioners?"

PERSECUTION OF DOCTORS

The meeting was told about persecution of doctors in Cuba Dr R L Luffingham (East Yorkshire) said that what the Cuban delegation had described to the World Medical Association had been confirmed Doctors in Cuba had been imprisoned for treating patients with views against the dictatorship, some had been beaten for refusing to disclose information, and armed police were placed outside doctors' surgeries President Baptista had not replied to a request from the World Medical Association to send independent observers The representative body carried an amendment making clear that it accepted the facts reported

MEDICAL WAR CRIMINALS

Dr Eric Townsend (Cornwall) moved

"That this representative body expresses its deep distress on learning that the Federal German medical authorities have seen fit to permit the reinstatement of a practitioner guilty of medical war crimes It instructs council to take whatever steps seem practical and effective to bring the views of the British Medical Association to the notice of those responsible for this cynical affront to the honour and high ideals of the true practice of medicine throughout the world"

Dr Townsend said that Dr Herta Oberheuser, a young fanatical Nazi doctor who volunteered to go to the notorious Ravensburg concentration camp, selected women for experiments by inflicting wounds and then deliberately infecting and neglecting these wounds She admitted that many of her patients died as a result of these experiments In 1947 she was sentenced to twenty years' imprisonment Her sentence was reduced in 1951 to ten years In 1952 she was released She had gone into practice near Hamburg

She was not alone Hans Eisele, from Buchenwald, was also again in practice Hans Bodo Gorgass, who in experiments on euthanasia killed thousands of victims in mental hospitals and who was sentenced to death but reprieved, was also in practice

Dr I H Milner (City) recalled that 23 S S physicians and scientists appeared before the U S Military Tribunal No 1 in Nuremberg They included Karl Gebhardt, head of the German Red Cross, and Herta Oberheuser 15 were found guilty, 7 were sentenced to death, 5 to life imprisonment, and Herta Oberheuser, the only woman, was sentenced to twenty years' imprisonment She had been "rehabilitated" and given a position of responsibility She admitted having herself administered injections of petrol to patients "Allowing this physician to practise places us in an invidious position in regard to members of the medical profession in Germany," declared Dr Milner

Dr I D Grant, chairman of the international relations committee, said that the committee had written to the Bundesarztekammer, and he read the reply it had received

"We German doctors deplore the fact that we have not the legal right in the Oberheuser case to withdraw permission to practise The Federal Chamber of Doctors has taken every step within the ambit of the law to prevent the practice of medicine by Dr Oberheuser" The Ministry of the Interior of Schleswig-Holstein had now instituted proceedings for the withdrawal of the approbation, and the German medical profession hoped that the withdrawal of the approbation would be pronounced and that the right to practise medicine would be taken away from Dr Oberheuser

Dr Grant added "Like everyone we are filled with horror that this woman should have been restored to the practice of medicine in Germany or anywhere else"

Dr Townsend asked permission to delete the words "Federal" and "medical" from the resolution As amended the resolution was carried without dissent

INDUSTRIAL COURT AWARD

Dr J B Tilley, chairman of the public-health committee, referred to the judgment of the Industrial Court that public-health doctors should be considered as part of the local-government hierarchy, and their salaries should not be considered in isolation, and that this was without prejudice to any claim that might be made by public-health doctors after the claims of all other local-authority officers had been settled "It is most satisfactory that the Industrial Court should have made pronouncement of this kind on a matter on which were not asked to give any opinion," he said The bility of the Whitley machinery breaking down was real

FULL-TIME SERVICE SOMETIMES?

Dr A J Macleod (Outer Isles) wanted an ad the motion from Harrow, moved by Dr J B Wrath Rowe, that the meeting was strongly opposed to a wh time salaried National Health Service, making it that this was "for general practice as a whole, with prejudice to what may be for the best in limited The Chairman did not ask for a vote on either motion amendment "I put it that we reaffirm our policy," h said The meeting agreed

PRESCRIBING IN GENERAL PRACTICE

Despite assurances from Dr Davies, several spoke in favour of a motion by City that the council should inquire into the whole question of freedom of prescribing in general practice Dr Alan Rezler said that every year hundreds of warning letters were sent to doctors, about

700 doctors were seen by regional medical officers, and a few were fined, some heavily "We wonder how many patients are sent to hospital solely to save the costs of prescription," he remarked "I suggest that the present freedom to prescribe is freedom to enter the field 'but beware of the bull'"

Dr B BURNS (Sheffield) declared that the much-vaunted freedom for prescribing was illusory In hospital even the most junior doctor, unlike the general practitioner, had carte blanche But Dr J S M ORD (Glasgow) opposing the motion, which was lost, thought younger men must be guided

TRANSFER OF PATIENTS

A motion that restrictions on the transfer of patients should be abolished was defeated Dr COLIN RUSS (C[illegible]) moved it Arguments in favour of the motion were that restriction encouraged complaints, and that the National Health Service patient should not have to ask permission, any more than a private patient had to

"MERIT AWARDS" IN GENERAL PRACTICE

Dr WAND appealed to the representative body to give guidance as to whether it wished a system of "merit awards" for general practice to be considered He explained that the Association had been asked by the Royal Commission to give consideration to some kind of incentive award

To obtain an expression of views, Dr R M S McCONAGHEY moved "That this meeting sees no objection to a 'merit award' system for general practice, providing a practicable scheme can be devised and subsequently approved by the representative body" An attempt to make this motion read that there was no objection to "an alternative method of remuneration" was greeted with cries of "No," and by a large majority the motion was approved

ELECTION OF G M C MEMBERS

Approval was given to the new method of selecting the Association's candidates for election as elected members of the General Medical Council The recommendation provides that a "postcard whip" sent to all doctors shall contain the names of every candidate seeking election, but with the names of those supported by the Association printed in heavy type

A I D

In the last two hours of an extended final session there was a long and rather emotional debate on artificial insemination by donor, a matter on which the platform appealed for guidance from the meeting

Dr L S KEENAN (Harrow) condemned any form of artificial insemination as unnatural Dr F W BELAM (Guildford) was opposed to artificial insemination by donor but not by husband Said Dr K M TOMLINSON (Gloucestershire) "To help one unhappy woman does not justify our help in the introduction of an almost certainly unhappy child" But Dr A BARKER (council) knew there had been a great deal of happiness in the right cases

Eventually the representative body resolved, while making no pronouncement on the non-medical aspects of A I D, to authorise the council to submit evidence to the Government committee on this subject, from the medical point of view, if so desired But it had already voted 101 in favour to 84 against an amendment by Dr C P WALLACE (Guildford), expressing "grave concern at the increasing practice of A I D"

AN EVALUATION OF TREATMENT OF DEPRESSIVE ILLNESS IN A DAY HOSPITAL *

MICHAEL CRAFT
M.D Lond, M R C P E, D.P M

LATE REGISTRAR, BETHLEM ROYAL AND MAUDSLEY DAY HOSPITALS, DEPUTY SUPERINTENDENT, ROYAL WESTERN COUNTIES HOSPITAL, STARCROSS, DEVON

DAY-HOSPITAL treatment in psychiatry was first described by Dzaghagarova (1937) and Dzaghagarova and Balabanova (1944) in Russia and by Cameron (1947) in North America These and subsequent articles have emphasised its cheapness and suitability for those of the mentally ill who are well enough to travel and spend nights at home

It has been suggested that day hospitals, by intensive treatment, may diminish the duration of such treatment in mental illness (World Health Organisation 1953) Be that as it may, it seemed desirable to compare the results of day-hospital treatment with those of conventional hospital care To this end three studies of Maudsley Hospital records were made Since depressive conditions form the bulk of those treated, it was decided to concentrate on them

The working of the Maudsley Day Hospital has already been described (Harris 1957) It admits only those who, but for the day hospital, would have needed inpatient admission

First Study

The first study concerned patients with depressive states who had had previous attacks of depression, for which they had been treated as inpatients In three years of Maudsley day-hospital practice 57 such patients were found In 5, however, the inpatient treatment had been recent—within twelve months—and it was thought that the two periods of treatment might have been for the same illness which had incompletely remitted 8 patients had had both day-hospital and inpatient treatment for the same attack, and in 3 further cases either information was inadequate or the illness was not depressive These 16 patients were excluded

In the remaining 41 patients the duration of day-hospital treatment was longer in 11 and shorter in 30 than the duration of mental-hospital treatment of their previous depressive illnesses The average for the 41 inpatient periods was 106 7 days, and that for the 41 day-patient periods 68 0 days The difference between these averages is similar to that obtained in another series discussed below and is explainable in almost identical terms In each case it was the earlier depressive episode which was treated on conventional inpatient lines Also the earlier attack may have been more severe There is conflicting evidence in the literature about the extent to which these factors would cause bias in the results

Second Study

The second study was based on female patients with depressive illnesses who completed treatment under the same physician as either inpatients or day patients in the three years ended May 4, 1956 The diagnoses were

---

neurotic depression, depressive phase of manic-depressive psychoses, involutional melancholia, and puerperal depression. Patients staying less than a week, those treated as both day patients and inpatients, and those receiving additional diagnoses of personality disorder, organic cerebral illness, or brain damage were excluded. Detailed notes of the initial outpatient attendance and other examinations on admission were available, and these were used to assess the depth of depression on admission on the following four-point scale:

Grade	*Retardation*	*Somatic disturbance*	*Registrar's comment*
(1) Mild	Nil	Minimal or none	Need for admission doubted
(2) Non-psychotic	Moderate	Poor sleep, early waking, some anorexia	Standard admission
(3) Psychotic	Severe	Severe insomnia, early morning depression, loss of weight	Seriously ill patient
(4) Stuporose	Mute	Stupor	Bed patient

For a retrospective series, previous rating-scales proved difficult to apply (Rowell 1951, Cohen et al. 1944, Lorr et al. 1951, Meyer 1951, Malamud and Sands 1947). The four-point scale worked well in the circumstances. Groups of day patients and inpatients with illnesses of similar severity were then compared as regards the time taken for recovery. 64 day patients and 69 inpatients, with depressions of similar severity on admission, were stated at discharge to be "recovered." 49 of the former and 38 of the latter were discharged within three months of admission, and it can be shown by χ^2 that this is a significantly greater number of day patients than inpatients where $0.02 > P > 0.01$. Day care is here again shorter than inpatient care.

Third Study

For the third study it was decided to form matched pairs of female depressives, each including one day-hospital patient and one inpatient. 43 pairs were matched for age, previous mental-hospital admissions, severity of illness by the four-point scale on admission, marital status and social class. The characteristics to be matched were decided on after perusal of twelve authors which proved the most helpful in assessing prognostic factors (Bond 1954, Dedichen 1946, Harris and Lubin 1952, Karagulla 1950, Lewis 1936, 1938, 1944, Lundquist 1945, Malzberg 1929, 1935, 1940, 1954, Ødegaard 1954, Pollock 1925, 1931, Rennie 1942, Robins 1954).

As an additional check regarding the depth of depression, the physician who had had charge of the patients was asked to rate the 43 pairs of notes according to the scale of severity. By χ^2 there was no significant difference ($0.5 < P < 0.3$) between his results and mine.

It was not possible to match for duration of illness before admission. 27 day patients and 31 inpatients had symptoms for less than six months before admission. Using χ^2 this was not significant at the 5% level. 25 day patients and 22 inpatients received electroconvulsion therapy, this difference also not being significant.

The results of treatment for the series were assessed by three criteria—length of stay in hospital, degree of recovery on discharge, and condition five months after discharge. The average duration of treatment of the day patients, together with their standard error, was 73.0±7.2 days, and of the inpatients 101.6±12.3 days. A direct comparison of these averages by the *t* test shows that P is just 5%. The statistician analysing the results felt that this figure was not significant, because the 5% level was only just attained and the spreads of the distribution being compared were most significantly different ($P < 0.001$), the *t* test being of doubtful validity in these circumstances.

The difference in the scatter of the results was almost entirely due to three high values for the inpatients. If these three values are deleted (and it is dangerous to discard observations unless there are strong external reasons for so doing), the remaining 40 inpatients give an average of 84.7±8.3 days. The comparison of this result with the 43 day patients, allowing for the different numbers, gave a value of P between 0.25 and 0.30. This is not significant.

Similar statistical arguments apply to the figures given in the first study for a different group of patients. Though the significance of the apparently shorter stay of the day patients is therefore doubtful, it is quite clear that *day treatment does not take longer than inpatient treatment.*

Degree of recovery with the matched series showed 26 day patients recovered at discharge compared with 28 inpatients, 14 day patients and 14 inpatients improved, and 3 day patients and 1 inpatient unchanged or worse. By χ^2 P lies between 0.8 and 0.7. This is not *significant.*

A follow-up was undertaken by personal interview five months after discharge and was successful with 41 day patients and 41 inpatients, 95% of the total. Within the five months 2 day patients and 4 inpatients had needed readmission to hospital. This difference is not significant. At the end of five months 30 day patients and 31 inpatients had returned to their previous output of work, whereas 11 day patients and 10 inpatients had reduced output. This also is not significant. Clinical rating-scales showed that at five months 23 day patients and 27 inpatients maintained recovery, 9 day patients and 7 inpatients remained improved, and 7 day patients and 6 inpatients were unimproved. Information was inadequate for 7 patients. By χ^2 P lies between 0.7 and 0.5, and there is no significant difference.

Comment

These retrospective studies can be criticised on the ground that the day hospital is most suited to manage the milder depressive illnesses and there would be a strong tendency for admitting physicians to forward the less-seriously ill for treatment. One might infer from this view that the milder illnesses would more rapidly recover. Only a trial with initial random allocation of patients would completely satisfy this criticism. It was to deal with this point that the rating-scale and the matched series were set up and an independent assessment was made of the severity of illness. It is felt that, so far as was possible, cases of equal severity were compared. In this context, however, it is worth noting that important studies by Rennie (1942) and Lundquist (1945) doubt whether there is a significant relation between depth of depression and duration of stay or outcome.

Summary and Conclusions

Three studies of Maudsley records are presented which indicate that many depressive illnesses were as effectively treated in the Maudsley day hospital as in the wards, judged by length of stay in hospital, degree of recovery on discharge, and a five-month follow-up. There is evidence that treatment in the day hospital shortens the length of stay in hospital.

I am indebted to Prof. Aubrey Lewis for his encouragement, to Dr. Arthur Harris for his help and permission to use the clinical material of the Bethlem and Maudsley Day Hospitals, and to Mr

Frank Downton and the late Dr Vera Norris of Leicester and London Universities for their statistical advice

LEPROSY RESEARCH FUND

This Fund, which is sponsored by the American Leprosy Missions, was founded in 1953 with the aim of linking leprosy to general medicine and to fundamental research and so attracting more workers to this important but neglected specialty To administer the Fund, but not to raise funds a committee was set up in England, of which Dr W A R Thomson is chairman and Dr R G Cochrane secretary

The Fund has not the money to finance large projects or research schemes, and its limited resources have been used to stimulate pilot research projects to test whether a particular problem is of sufficient importance to warrant asking for the backing of one of the large Foundations The Fund is in touch with many institutions all over the world, and also arranges small clinical trials of new drugs to collect preliminary data before comprehensive trials are launched

Projects which the Fund has backed during the past five years include the following

Dr Graham Weddell, with a grant from the Fund, visited India in 1951 to investigate the possibility of using leprosy as a tool in the research of cutaneous sensibility As a direct result of his work, Dr David Jamison was appointed, in 1957, to a research fellowship sponsored by the Royal Society, to undertake more detailed research in the histopathology of leprosy, with particular reference to cutaneous sensibility

In 1955 the Fund raised the money for Dr E M Brieger of the Strangeways Laboratories, Cambridge, to visit the African Inland Mission Hospital at Oicha in the Belgian Congo to investigate the possibility of using electron microscopy in the study of the life history of the *Mycobacterium lepræ* The value of this investigation is shown by the fact that the Colonial Medical Research Council has now given a grant for Dr Brieger s work

The Fund proposes to organise a reference laboratory and a registry of histopathology which will ultimately contain complete clinical, photographic, and histological records of types and groups of leprosy in the different parts of the world The cost of organising this unit will be about £2300 a year

The address of the Leprosy Research Fund is 11A, Weymouth Street, London, W 1

> " Honest compassion has no coefficient in the world of statistics—at least up to now An unreliable guide to policy on its own, it nevertheless has the loudest voice and draws the warmest cheers I suppose the majority of young parents would prefer that a million mentally disordered people were permanently ' locked up ' than that harm should befall their children The development of civilised society has always depended on the extent to which considerations of that kind can be subordinated to the common good ' —C H ROLPH, *New Statesman*, July 5, 1958, p 6

Public Health

OCCUPATIONAL HAZARDS IN THE BONE-MEAL INDUSTRY

ROBERT LAMB
T D , B Sc , M D Glasg , D P H
PHYSICIAN, GATESIDE INFECTIOUS-DISEASE HOSPITAL, GREENOCK

BONE fertiliser is a well-known source of anthrax infection in animals and occasionally in man In Greenock there is a factory which produces animal charcoal for use in sugar refining This factory imports bones from India, Pakistan, and the Argentine As delivered these bones have already been broken up into fragments varying in size from 2–3 in long to granules about $^1/_4$ in in diameter The raw bones are further broken up in crushing mills, and thereafter the crushed material is passed over moving metal screens which sort it into three grades of granularity before it is reduced to charcoal in the ovens

The very fine bone dust remaining at the crushing mills is collected and sold as bone fertiliser Precautions against inhalation of this fine dust include the provision of face masks for the workers and the use of exhaust fans erected over the crushing-plant. The workers wear protective clothing, but the fine dust penetrates through this clothing and reaches the underclothing Bone dust is to be found everywhere in this factory, even in the offices

This description of the heavy concentration of bone dust is important, because frequent sampling of the raw bones, the crushed bones, and the bone dust has shown that the spores of virulent anthrax bacilli are present Such sampling has only been carried out over the past five years, during which cases of cutaneous anthrax have occurred among the workers An official of this firm assures me that the source of supply of bones has been the same in the past twenty-eight years Further, the only cases of cutaneous anthrax he has knowledge of are the four described here

Apart from cutaneous anthrax I have encountered two cases of empyema in workers in this factory In both cases the infecting organisms were of the clostridial group These patients were employed at the crushing mills and were therefore exposed to heavy concentrations of bone dust

Cutaneous Anthrax

Table I shows the age, sex, and occupation of the four patients with cutaneous anthrax

TABLE I—DATA ON FOUR CASES OF CUTANEOUS ANTHRAX

Case no	Sex	Age (yr)	Occupation	Site	Date admitted
1	M	29	Labourer	Side of neck	Dec. 1955
2	M	47	Lorry driver	Back	April 1956
3	F	53	Sack repairer	Over rt breast	Nov 1957
4	M	29	Process worker	Rt malar eminence	March, 1958

Case 1 —This man, aged 29, was admitted forty-eight hours after a painless red papule had appeared on the left side of his neck. He was a labourer employed in carrying sacks of raw bone fragments to the crushing mill, he stated that he carried these sacks over his left shoulder It was likely then that either he had an abrasion on the left side of his neck or an abrasion was produced by a spicule of bone protruding through a sack

On examination the sore had a black necrotic centre about 1/4 in in diameter There was much swelling of the tissues around this sore and regional adenitis Smears of serous exudate taken from this sore were positive for *Bacillus anthracis* The patient was afebrile and non-toxic

Treatment and progress—Phenoxymethylpenicillin 125 mg was administered six-hourly The lesion enlarged for two days, reaching a maximum size of 2 in × 5/8 in , around the necrotic centre a ring of vesicles appeared After three days the lesion began to regress The patient was discharged after fifteen days He was seen after twenty-eight days as an outpatient when the sore was granulating, but it was obvious that a scar would result

Case 2 was a lorry driver, aged 47, who delivered sacks of bone meal from the factory, loading the sacks on to his back from the tailboard of the lorry He was admitted with a forty-eight hour history of pain and swelling over the left side of his back On the day of admission he felt nauseated and shivery and had to go to bed

On admission he looked very toxic, and his blood-pressure was 80/50 mm Hg, temperature 104°F The sore consisted of a black necrotic centre about 1/4 in in diameter, and there was much lardaceous œdema surrounding it for a radius of 8–10 in , with gross hæmorrhagic infiltration into this œdematous zone The sore spread for seven days and the hæmorrhagic infiltration became more extensive

Treatment and progress—Phenoxymethylpenicillin 250 mg was administered six-hourly After three days the patient became afebrile and his general condition was much improved He was discharged after twenty-eight days with a deep ulcer where the eschar had separated

Case 3 was a woman, aged 53, employed as a sack repairer, before the sacks were submitted to her for mending they had been cleaned by vacuum suction Five days before admission she noticed a pimple over her right breast On the day of admission she became collapsed and dyspnœic

On admission she obviously had severe peripheral circulatory failure, the blood-pressure was not recordable The sore was typical of a malignant pustule, there was much œdema and hæmorrhagic infiltration over the right breast

Treatment and progress—In view of the circulatory failure an intravenous saline drip containing noradrenaline was set up, and intramuscular crystalline penicillin 250,000 units six-hourly was administered After twenty-four hours there was no improvement in peripheral circulation, and although the serum-potassium and serum-sodium levels were normal it was considered advisable to replace the noradrenaline by hydrocortisone Despite this change extreme peripheral failure persisted for sixty hours, during which the blood-urea rose from 81 to 108 mg per 100 ml Thereafter she began to improve, but, as in the other cases, there was some extension of the lesion for the first three to four days After nine days a secondary sore appeared some 3 in below the anthrax sore, this sore consisted of a blood-filled vesicle, and was considered to be a trophic lesion due to the extensive œdema further precipitated by the prolonged hypotension Smears of the original sore were positive for *B anthracis*, but as expected the "trophic" sore was negative Blood-cultures were sterile During her period of peripheral failure she complained of precordial pain, but an electrocardiogram was essentially normal This patient was discharged after five weeks with both sores granulating Scarring is to be expected

Case 4—A man, aged 29, who worked at the crushing mill, was admitted with a thirty-six-hour history of a sore over the right malar eminence He had regarded the sore as a boil, but became worried when his face began to swell On admission he did not look ill and was afebrile The lesion was a typical malignant pustule with surrounding œdema and regional adenitis He was treated with phenoxymethylpenicillin 250 mg six hourly, and the lesion began to regress within twenty-four hours The resultant scar will be small

Clostridial Empyema

Table II shows the ages and occupations of two men in whom empyema due to clostridial infection developed

TABLE II—DATA ON TWO CASES OF CLOSTRIDIAL EMPYEMA

Case no	Sex	Age (yr)	Occupation	Site	Date of admission
5	M	30	Process worker	Rt empyema	March, 1953
6	M	41	Process worker	Lt pneumonia plus effusion	March, 1958

While it seems strange that clostridial organisms should infect previously healthy lungs, I am convinced that this was so in each of these cases Neither patient had any history of chronic or recent pulmonary infection In each case large gram-positive bacilli were seen in large numbers on direct examination of pleural fluid and specimens of sputum

Case 5—A man, aged 30, employed at the bone-crushing plant, was admitted with a ten-day history of right-sided chest pain, preceded by rigors, and of cough which was at first unproductive Six days before this illness began typical herpes zoster had developed over the right side

On admission he looked very ill and his temperature was 102 F Healing herpes zoster lesions were noted in the right hypochondrium The physical signs of a right-sided pleural effusion were present Aspiration of the right chest yielded 16 oz of chocolate-coloured fluid with a glue-like odour Direct examination of this fluid showed large gram-positive bacilli Sputum samples, too, were positive for clostridia Clostridial organisms were recovered on anaerobic culture Later these were identified as *Clostridium tertium*

Treatment was by daily aspiration and instillation of oxytetracycline together with oral oxytetracycline

Progress—Daily examination of the pleural fluid showed a gradual disappearance of the organisms, after seven days no organisms were seen and the fluid was sterile Nevertheless, the fluid persisted for six weeks, and during the last two of these weeks closed pleural drainage was in operation He remained febrile for four weeks, but his general condition improved steadily Chest radiographs showed considerable collapse of the right lower lobe with air and fluid in the pleural space What was reported as air was considered to be gas from the organisms, since the aspiration was carried out carefully with a two-way tap Later radiographs showed improvement, and in eight weeks the only remaining lesion seen on the radiograph was obliteration of the right costophrenic angle The patient was then discharged and is still well

Case 6—A man, aged 44, also employed at the bone-crushing plant, was admitted with a history of an influenza-like illness which lasted for seven days His principal symptoms were severe frontal headache and left-sided chest pain aggravated by movement, deep breathing, and coughing, the cough was productive and sputum rusty There was a previous history of left-sided dry pleurisy twenty years ago

On admission he looked anxious and was dyspnœic and slightly cyanosed The blood-pressure was 130/85 mm Hg There was no evidence of any cardiovascular disease The physical signs of a left-sided pleural effusion were present 18 oz of thin brown fluid was obtained by aspiration of the left chest Direct examination of this fluid showed numerous large gram-positive bacilli

Treatment—In view of the patient's occupation and the experience of the previous case he was treated by oxytetracycline both intrapleurally and orally

Progress—Anaerobic culture of the fluid showed that the organisms were of the clostridial group Further investigation suggested that they might be *Cl œdematiens*, but this was not proved and the organisms have up to the present not been specified A chest radiograph confirmed the presence of pleural fluid, and also showed underlying consolidation of the left lower lobe Specimens of sputum also contained clostridial organisms The patient was febrile for twenty days, but at the end of that time was very much improved After four weeks no further fluid could be obtained by aspiration although a chest radiograph at this time suggested that fluid still remained After nine weeks chest radiography showed extensive opacity over the left lung field, but this was thought to be due mainly to pleural thickening The patient is now considered to be well and only the signs of pleural thickening persist

It is not uncommon to find clostridial organisms in the sputum of patients with chronic pulmonary infection The two patients here described were not suffering from chronic bronchitis; Only one of them had a history of previous chest disease—pleurisy twenty years before The pleural fluids on direct examination showed numerous clostridial organisms Both workers were employed in an atmosphere heavily laden with fine bone dust, which on repeated sampling contained the spores of *B anthracis*, although no specific examinations for clostridial spores were made it is reasonable to assume that such spores could also be present Indeed I have been informed that in investigations of bone meal for anthrax, clostridial growth has to be suppressed before inoculating guinea-pigs (J H C Walker, personal communication) It is remarkable, however, that hitherto no cases of pulmonary anthrax have occurred among the workers in this factory

Summary

Four cases of cutaneous anthrax among workers in a bone-meal factory are described One of the patients had severe peripheral circulatory failure, although there was no evidence of septicæmia

Two cases of empyema presumably due to clostridial infection suggest that such infection may be a further hazard among workers in this industry

My thanks are due to Dr P Browning for identification of *Cl tertium* in one of these patients, to Dr J G Goudie for the bacteriological examinations in the anthrax patients, to the Central Veterinary Laboratory at Weybridge, Surrey, for their reports on the various bone samples submitted for examination for anthrax infection, and to Dr J Ramage of Larkfield Hospital, Greenock, for electrocardiographic examination of case 3

ANTHRAX AND BONE-MEAL FERTILISER

D M GREEN
M D St And
LECTURER IN BACTERIOLOGY, UNIVERSITY OF ST ANDREWS,
QUEEN S COLLEGE, DUNDEE

W M JAMIESON
M D St And, M R C P E, D P H
PHYSICIAN-SUPERINTENDENT, KING S CROSS HOSPITAL, DUNDEE

WE have previously reported anthrax in six patients in whom the infection was derived from bone-meal fertiliser (Jamieson and Green 1955) We expressed the view that bone-meal used in this country should be rendered safe from the hazards of anthrax In February, 1957, the Minister of Health announced the setting up of a committee of inquiry

> "To consider the existing legal provisions concerning the importation of goods infected or likely to be infected with anthrax and the precautions to be taken in connection with such imported goods for the protection of the health of persons and to make recommendations" (see *Lancet* 1957)

Since our last report, we have seen four further cases of anthrax One patient was a veterinary surgeon who contracted the disease through contact with an infected animal The other three gave histories of having handled bone fertilisers, and *Bacillus anthracis* was isolated from samples of bone fibre handled by one of them (case 3)

Case-reports

Case 1 —A farm labourer, aged 28, was admitted to hospital with a typical anthrax lesion on the dorsum of the left hand He had cut the hand 3 weeks before, this wound had healed, but 2 days before admission he had scratched the part again, and this was followed by the development of the typical lesion He had been handling a "commercial fertiliser" which probably contained bone-meal Direct microscopy of material from the lesion showed gram-positive bacilli morphologically resembling *B anthracis* Culture and guineapig inoculation were negative The patient was treated with combined penicillin and streptomycin and recovered completely

Case 2 —A farm grieve, aged 53, was admitted to hospital with a lesion on the right side of neck which was typical of anthrax after the acute phase 3 weeks before, he had noticed a small "boil" on the neck, and this had progressed, causing much swelling of neck and face His own doctor had treated the lesion with penicillin Bacteriological examination was not carried out until his admission to hospital, and, not surprisingly, this was negative, microscopically and culturally, for *B anthracis* The patient recovered fully About the time of developing the lesion, he had been actively engaged in spraying fields with bone-meal fertiliser Samples of the fertiliser were not obtained for examination There had been no animal deaths on the farm

Case 3 —A boy, aged 15, was employed as a nursery-worker He was admitted to hospital with typical anthrax of the left cheek 10 days before he had scratched his face and this was followed by the development of the malignant pustule Microscopical examination of material from the lesion showed organisms morphologically resembling *B anthracis*, but culture and animal inoculation were negative He recovered completely after treatment with combined penicillin and streptomycin This boy had been preparing soil for growing tomato plants, which involved the use of bone-fibre While some of the workers wore gloves for this job, he himself had not done so Four samples of the material used by him were obtained, and *B anthracis* was isolated from three of them

Method of Isolation of B anthracis

The four samples of bone-meal fertiliser consisted of three samples of bone fibre from 1 cwt (112 lb) bags—very dusty material with fibres in it—and one sample of bone-meal from a $1^1/_2$ cwt bag which looked like "meal" with fibrous material The source was either Indian or Argentinian, or possibly a mixture from the two sources The samples were treated in the following manner

The material was shaken up with sterile distilled water (25 g in 100 ml) and after standing for two hours, with occasional shaking, the supernatant fluid ("wash') was heated to 70°C for 10 minutes Pour plates were made of varying amounts in 'Yeastrel' agar, which gives deep colonies of *B anthracis* of typical appearance (A J H Tomlinson, personal communication) The formula for yeastrel agar was as follows

Eupeptone no 2	5 g
Yeastrel	3 g
Agar (Davis)	10 g
Distilled water	1000 ml

Autoclave at 15 lb for 15 minutes to dissolve, make to pH 8 2 Steam 30 minutes Filter through 'Chardin', if necessary adjust to pH 7 6 Sterilise in autoclave at 10 lb for 10 minutes

Cultures were also made in the selective medium described by Pearce and Powell (1951) In one of the samples of bone fibre, *B anthracis* was isolated from the yeastrel agar The strain gave a characteristic appearance in a Craigie tube and killed a guineapig, which showed typical macroscopical and microscopical appearances and a McFadyean's reaction

The remainder of the wash was centrifuged, and half the deposit was injected into a guineapig which had been protected 24 hours previously with polyvalent gas-gangrene containing *Clostridium perfringens* antitoxin 2000 units, *Cl septicum* antitoxin 1000 units, *Cl œdematiens* antitoxin 2000 units, and tetanus antitoxin 500 units

In the case of the three samples of bone fibre, the guineapigs died between 24 hours and 72 hours after injection Animals which died at 72 hours showed typical macroscopical and microscopical appearances of anthrax, and *B anthracis* was isolated from the blood and tissues In two animals which died 24 hours after the injection the necropsy appearances were typical of gas-gangrene infection, but in one of them cultures from the heart blood and site of inoculation gave isolations of *B anthracis*

No isolation was made from the $1^1/_2$ cwt bag of bone-meal by either animal inoculation or cultural methods

The strains isolated were tested in vitro by a plate technique using Evans' ' Sentest ' tablets, and they were all sensitive to penicillin, streptomycin, aureomycin (chlortetracycline), oxytetracycline, and erythromycin

Comment

Since 1952 ten cases of anthrax have been admitted to King's Cross Hospital In four cases there is bacteriological confirmation that the patients had handled infected bone-meal fertiliser, strong presumptive evidence of bone meal as the vehicle of infection was present in a further five, one case was not directly associated with bone-meal The infected bone material was imported These findings may be of interest in view of the Committee of Inquiry presently examining the problem of goods likely to be infected with anthrax

Davies and Harvey (1955) demonstrated *B anthracis* by animal inoculation in 5 (12%) of 41 cargoes of imported bone-meal over 18 months They pointed out that the infectivity for man is probably low since only two cases of anthrax were seen during the 18 months In the present series the patient with whom the bone fibre was associated was not the only person to handle the material, but he appears to have been the only one infected

Summary

A history of having handled bone-meal products was given in three out of four cases of anthrax In one case samples of bone fibre and meal were obtained, and the bone fibre yielded *B anthracis*

The bone-meal products were apparently Indian or Argentinian in origin, or a mixture of both

The strains isolated were all sensitive to penicillin, streptomycin, aureomycin, oxytetracycline, and erythromycin

We should like to thank Prof W J Tulloch for facilities and Dr A J H Tomlinson for giving us details of the yeastrel agar and permission to describe it, Dundee Sanitary Department for obtaining the bone fertiliser and for information concerning its origin, and Miss I M B Graham for technical assistance

Addendum

We have seen within the past four weeks a further case of anthrax The patient was a seedsman aged 17 years with a typical lesion on the right forearm We have been able to demonstrate *B anthracis* from a sample of bone-meal handled by him, both by isolation in yeastrel agar and animal inoculation

In England Now

A Running Commentary by Peripatetic Correspondents

It is now some time since we became tired of writing scientific papers in which nobody was interested We felt that our psyche was cramped by these endless processions of *facts*, the limitless calvacade of introductions, techniques, results, discussions, and summaries, with their subsidiary acknowledgments, references, and illustrations It came to us that what we needed was an outlet for our personality, a larger canvas for our brush We determined to let our soul take wings We would write a book

Initially we detected a pervading apathy among the various publishers we attempted to favour with our custom "We recognise, of course," their letters began, "that the work you have been doing is of first-rate importance, but " Eventually, however, we succeeded in discovering a kindly firm who were basically sorry for us, and obtained an imposing-looking memorandum covered in red seals, in which we were hereinafter described as the author

The first proofs arrived heavily annotated in a fine Italianate *script by the translator* "*Cytoarchitectonics of the Umbilicus*," we had written baldly, "1 The Philosophical Background" This had now become "*Perp Titl 258 12 pt cap #d* $1^1/_2$ *pts R4 rule 24 ems Sub Perp 239 18 pt fig ital caps No Os*", and we were delighted to find ourselves so much in the technical swim We discoursed at length to our colleagues at morning tea on the relative advantages of Times bold face and Garamond in the production of scientific literature, and at lunchtime we went out and bought a spotted bow tie In the afternoon, however, we were mildly dashed to find, lurking among the pages, little interdepartmental publisher's messages They began innocently enough with "*Margin sheet pl*", but soon we began to detect a somewhat censorious, hectoring attitude "Charlie," read the second, "doubtful Latin p 15" Others were briefer, but not less to the point "C P," they said, marking our favourite purple passage, "*? constr Yrs* E R" *After a time relations between* C P and E R became slightly strained, and a brisk argument developed (over our prostrate body) on a grammatical point on p 127 But on the whole we saw no cause for serious alarm, and we relaxed into a happy daze of authorship

Our first intimation that all was not well came with the arrival of the first press copies, in a parcel bearing the bold-face label OF NO COMMERCIAL VALUE Since then we have seen all too clearly what they meant The reviewers have on the whole been tolerant, but they have made it clear that this has been a difficult task "Too long," they said, stifling a yawn "Too short," said others impatiently "Too detailed," said the clinical types, throwing down their pens to dash off to a subtotal viscerectomy "Too vague," said the back-room boys with scarcely concealed contempt "Too orthodox, too speculative, too turgid, too simple, unsuitable for students unsuitable for teachers, unsuitable for research workers, unsuitable "

The other day a distinguished guest was rummaging about in our library of *Penguins* when we heard our youngest child say to him in a sad meditative voice, "*My Daddy wrote a book* once It didn't sell "

* * *

Great progress is being made in medical knowledge and, for this, much credit must go to the epidemiologists who patiently ferret out fresh factors in the production of disease Thus in recent years we have learnt that the use of tobacco may well give us cancer of the bronchus or, at the best, chronic bronchitis, and, as if these were not enough, the smoker is now threatened with cancer of the bladder for his indulgence The comparatively virtuous glutton has been warned that his habits may lead him to a coronary infarct Resolute tipplers have shrugged aside fibrotic threats to the liver and neoplastic ones to the larynx only to find that the epidemiologists now promise them an increased risk of lung cancer because of prolonged residence in stuffy bars and drinking dens

It is not surprising if some of us are beginning to regard epidemiologists with considerable disfavour, for every fresh discovery of theirs only intensifies our chronic anxiety state But, to be fair, we must except the Pneumoconiosis Research Unit experts who cheered us up somewhat by reporting that inhalation of coal dust in moderate quantities would improve lung function. We are now wondering if addiction to coal-dust snuff could beneficially take the place of our present weaknesses

* * *

There is no doubt that convalescence broadens the scope of one's reading Never before have I had time to study those glossy circulars from the drug firms After carefully excluding those dangerous envelopes concealing samples of tablets I used to distribute all circulars, exactly, among the younger members of the family at breakfast (And woe betide me if one found more blotters than the other) But now the circulars come up to the bedroom with the breakfast tray and form part of my morning literary activity

The drug firms may not always quote the price of their product, but even the Hinchcliffe Committee would acknowledge that on occasion they are candid friends For instance we are told that one drug—with a reputation in tuberculosis but also useful in a variety of other diseases—has side-effects including constipation, difficulty in micturition, orthostatic hypotension, insomnia, impotence, headaches, and dizziness As if that were not enough, *pour encourager les autres*, there is also the chance of having muscle tremors, peripheral neuritis, and epileptiform attacks And finally the *coup-de-grâce*—jaundice.

There is a lot to be said, sometimes, for confining oneself to the disease with which one starts

* * *

Lincoln, in Massachusetts, U S A , is a little town close to the battlefields where the shot " heard round the world " was fired and English soldiers fought Englishmen " to keep the past upon its throne " When we moved to Lincoln as temporary summer residents, we were warned that even though we owed our allegiance to Her Majesty the Queen, we would have to take part in the town's annual Independence Day parade

At 10 A.M on a brilliant July 4 morning the parade moved off, led by the white-helmeted band of the National Guard and immediately followed by the town's oldest and newest fire-engines with sirens a-howling Then came a long line of symbolic floats carrying Lincolnites, old and young, in fancy dress We modestly brought up the rear in a Hillman Minx, its front decorated with a Union Jack and the boot surmounted by the Stars and Stripes and the Union Jack fluttering in unison In the hope of furthering Anglo-American relations, we had attached large placards bearing the jingles " 1775 but we're still alive " and " 1958, now we cooperate "

As we slowly drove along the route, the faces of the crowd looked puzzled and the applause was rather thin, so that our chances of winning any kind of prize seemed remote Then, at the last moment, just before we reached the judges' stand, we heard a loud voice " Guess they must be from the South " We treasure our third prize greatly

The echoes of that shot so many years ago are dying away

* * *

Science fiction has occasionally dealt with the psychiatric aspects of lunar voyages, and now that recent reports of plans to send rockets to the moon suggest that space travel may soon cross the line between fantasy and reality, is it not time to consider a rejuvenation of the term " lunacy " in psychiatric nomenclature? Perhaps a case could even be made for a lunatic syndrome, manifested by a morbid preoccupation with space travel, the presence of stellar phosphates in the urine, and, in the fully developed case, distortion of the features resulting in moonface Treatment of " moonshine " as it might come to be called colloquially, would probably be by administration of drugs such as 'Lunamil' or 'Lunatil' (one tablet three times a light-year) or by a process of conditioning by which the patient would be brought to earth

Letters to the Editor

THE DENTAL SERVICE

SIR,—Your leading article of June 21 discusses how dentists can be induced to give more of their time to the "priority classes"—children and expectant and nursing mothers But you do not mention the only way in which the profession in this country can provide adequate dental care for the whole population and at the same time recover its status I am speaking of the proper use of the right kind of ancillaries

Most dental students, on qualification, leave their hospital with high ideals and the ability to do, albeit slowly, almost everything a dental surgeon can do Our job can be very interesting, and the training we receive at hospital lays emphasis on its most interesting aspects—incidentally those which require intelligence and mental skill But what now happens when the young man gets into general dental practice? He finds immediately that the one part of National Health Service dentistry which is completely unpaid is the exercise of diagnostic ability and the use of the mental skills towards which his hospital training has been largely directed He finds that he is doing piecework and that his income for the rest of his career will be tied irrevocably to his output—regardless of its standard Thus committed for life to routine backbreaking work, paid at piecework rates, can he any longer be truly described as a professional man?

The alternative is not, as some of my colleagues think, higher pay for the same job—which is in any case unattainable—but a change in the pattern of our work No doctor would consider making surgical boots for his patients, or carrying out the many mechanical and semi-mechanical procedures necessary in treatment He has working for him a host of ancillaries—physiotherapists, radiographers, instrument-makers, nurses, and the like This is the way that dentistry also must go if it is to remain a profession Instead of deteriorating into hack workers, we dental surgeons must develop into a prescribing profession, in which we ourselves undertake only the more advanced procedures

There is in fact only one way to regain our proper position, and that is that we ourselves should plan and undertake, slowly and deliberately, the incorporation into dentistry of the right kind of ancillaries—not half-trained dentists, but fully trained technicians in one branch of purely technical dentistry These ancillaries would work under conditions laid down by the profession itself

Not only would this give a better service to the nation, and a better status to the profession, but it would also enable us to reverse the adverse pattern of earnings repeatedly pointed out in reports upon our profession, and enable dental surgeons, like physicians, still further to increase their skill and value to the community with experience

I am sure that ancillaries, properly used, are for the good of the profession, and it is up to us to see that those already legalised, and any that may be legalised in the future, are properly employed to increase both the efficiency and the status of dentistry in this country

London, W 1 J. H HOVELL

CHRONIC DISSECTING ANEURYSM OF THE AORTA

SIR,—The interesting report by Mr Eastcott and Dr. Sutton (July 12) calls for comment

(1) They speak of the diagnosis of dissecting aneurysm as "being rarely made" This is no longer true With the increasing recognition of the clinical signs of dissecting aneurysm it is becoming possible to diagnose the majority of cases during life (as their case was, by Professor Rosenheim) Of the last 34 cases seen at the Radcliffe Infirmary (24 confirmed at post-mortem, 5 having died at home and 5 being still alive) a correct clinical diagnosis was made in 21

(2) Radiological signs can be useful, even diagnostic[1] Widening of the aortic shadow as compared with previous films may, as Mr Eastcott and Dr Sutton suggest, be open to misinterpretation, but it is often a most helpful sign So is the appearance of calcification an abnormally long way in from the edge of the aortic knuckle

(3) The fact that a dissecting aneurysm extends from above to below the renal arteries does not necessarily, or even probably, mean that there is any interference with the blood-supply to the kidneys The dissection may not embrace the whole circumference of the aorta and it seldom extends into branch arteries, so that, although the dissection may surround the origin of the renal, or other, artery its lumen is not narrowed

(4) If the diagnosis of dissecting aneurysm has been made on clinical and radiological grounds one wonders whether it is wise to attempt to confirm it by arteriography The arteries of patients who have died from dissecting aneurysm are often friable, an arterial wall remote from the site of dissection can often be split into two layers by quite gentle rubbing Histological examination usually reveals marked cystic medial necrosis Although no reports have been published, so far as I know, of harm resulting from arteriography in cases of dissecting aneurysm it appears to be a risky procedure

INFLUENZAL ENCEPHALITIS

SIR,—We have read with much interest the accounts of encephalitis and neurological disorders associated with influenza by Dr Flewett and Dr Hoult, and Dr McConkey and Mr Daws, in your issue of July 5

May we draw the attention of pathologists to the importance of both virus studies and histological examination of the brain in all influenzal deaths, because it seems likely that some cases of influenzal encephalitis are missed at necropsy?

All are probably manifestations of the same pathological process, but further studies as suggested are still necessary to establish this Fatal cases of this important form of encephalitis should be correlated with the histological classification of encephalitis described by Greenfield[2] Complicated neuropathological techniques are not necessary for a diagnosis, but the brain should be fixed suspended in formol saline before sectioning The histological picture of hæmorrhagic leucoencephalitis is very characteristic The cortex and basal ganglia are spared, and the lesions in the white matter are of five chief types

(1) Necrosis of vessel walls including both small veins and arteries[3]

(2) Œdema of perivascular distribution with degenerative changes in the astrocytes

(3) A perivascular leucocytic exudation which becomes monocytic at a later stage

(4) Zones of perivascular demyelination containing excess microglial or histiocytic cells

(5) Perivascular ball or ring hæmorrhages

Meningeal infiltration by neutrophil leucocytes, lymphocytes, and histiocytes, which is often quite heavy, is also observed

These lesions are all readily recognisable in paraffin sections stained by routine hæmatoxylin and eosin They should be searched for in every case

Since 1953 we have seen 6 cases of encephalitis, of these, occurred during influenzal epidemics The 3 that came t necropsy all showed the histological picture we have described Greenfield[4] has obtained influenza virus A from the pulmonary lesions of a similar case but not from the brain W therefore agree with the view expressed in your annotatio that this type of encephalitis is the result of influenza W do not feel that such post-mortem findings can be explained by "severe anoxæmia and venous congestion" Also, w would like to point out that in most fatal cases of hæmorrhagi leucoencephalitis[4, 5, 6] the cerebrospinal fluid at some time ha shown a leucocyte count of several hundred per c mm and correspondingly increased protein This was our experienc also

Finally, we await with interest the report of the histo logical examination and classification of the brain in th first case described by Flewett and Hoult, from the lung of which influenza virus was isolated

Royal South Hants Hospital,
Southampton

R A GOODBODY
R J McGILL

INTESTINAL ABSORPTION OF VITAMIN B_{12}

SIR,—Dr Heathcote and Dr Mooney (May 10) hav suggested that vitamin-B_{12}-peptides are absorbed from the small intestine by a process of diffusion across th intestinal wall It occurred to us that this hypothesis could be tested by examining the intestinal wall for th presence of such peptides

We have, therefore, fed radioactive vitamin B_{12} to four rat and, in each case, after 1 hour, have removed the portion o intestine which contained nearly all of the radioactivity taken up in this time The length of intestine removed was opened by a longitudinal cut, washed, and then homogenised in saline The homogenate was ultrafiltered through Visking membrane Had vitamin-B_{12}-peptide complexes been present, they would have passed into the ultrafiltrate and an appreciable amount of radioactivity would have occurred in this situation In actual fact the radioactivity in the ultrafiltrate was only a few per cent of the total uptake We can assume, therefore, that vitamin B_{12} in the process of absorption is bound in such a way as not to be ultrafilterable, and that it is not bound to a peptide The small amount of activity we found in the ultrafiltrate could be explained in terms of a dissociation equilibrium

Examination of the intestinal contents revealed a somewhat greater proportion of ultrafilterable vitamin B_{12} This, of course, may be the vitamin in the free state, but equally well could be a peptide complex

Our observations, therefore, lead us to conclude that the vitamin is not absorbed as a peptide complex They do not, however, exclude the concept that vitamin-B_{12}-protein complexes are broken down to vitamin-B_{12}-peptides in the intestine by a process perhaps involving intrinsic factor[7] and that the vitamin is then transferred to a protein acceptor in the intestinal wall Studies of vitamin-B_{12} binding by intrinsic factor preparations (Latner and Raine, unpublished observations) make it unlikely that binding to intrinsic factor itself is a preliminary to absorption

We should also like to point out that analysis in terms of the response at the 15th day[8] of the clinical results published by Dr Heathcote and Dr Mooney indicates that relatively small quantities of vitamin B_{12} were absorbed This too can be taken as evidence against the absorption by simple diffusion of unaltered vitamin-B_{12}-peptides, since the amounts of vitamin absorbed were very small fractions of the total amounts administered

---

[1] Pyke, D A Post-Grad med J 1956, 32, 7
[2] Greenfield, J G Recent Advances in Clinical Pathology London, 1947

[8] Campbell J A, McLaughlan, J M Vitamin B_{12} and Intrinsic Factor I Europäisches Symposion, Hamburg 1956, p 258 Edited by H G Heinrich. Stuttgart

We have, of course, yet to see the proof that Dr Heathcote and Dr Mooney were actually administering a vitamin-B_{12}-peptide and not a mixture of the free vitamin and a peptide In our opinion, the absorptions they obtained might well be expected from the administration in similar dosage of vitamin B_{12} alone, and control investigations are badly needed

DILUTION ANÆMIA

SIR,—The "physiological anæmia of pregnancy" is due to an increased plasma volume[1-4] Likewise, in chronic myelogenous leukæmia increased plasma-volumes have been found[5,6]

It is conceivable that low concentrations of hæmoglobin (Hb) in the peripheral blood may be explained as dilution effects in other states Such patients may have a normal amount of total body hæmoglobin (THb) (i e, 1·12 g per kg in males and 0·86 g per kg in females) and an increased total blood-volume

FOUR CASES ILLUSTRATING DILUTION ANÆMIA

Clinical diagnosis	Hb concentration	Calculated normal THb (g)	Actual THb in g (% of calculated normal)	Calculated normal blood-volume (ml)	Actual blood-volume in ml (% of calculated normal)	No of blood-transfusions given
Chronic nephritis with secondary anæmia	72%	339	350 (*106*)	2400	3500 (*146*)	>15
Postural hypotension with anæmia*	61%	592	556 (*94*)	3800	5900 (*155*)	>10
Myeloma	65%	405	449 (*111*)	2900	4800 (*165*)	23
"Hepato-megalic anæmia"	62%	625	591 (*95*)	4100	6200 (*152*)	>12

* This case has been reported previously[7-9]

Hb, THb, and blood-volume (estimated same day) in 4 patients Hb 100% for males = 15·4 g per 100 ml., for females 13·9 g THb determined by the alveolar carbon monoxide method[10], normal blood-volume = normal THb ÷ normal Hb concentration.

It is questionable whether it is possible or even desirable to increase the THb above the normal amount in such cases, in an effort to make the hæmoglobin concentration normal, by giving blood-transfusions, and it does not seem to be known whether adequate circulatory function or even the feeling of wellbeing is more dependent on the THb (i e, total red-cell volume) or on the hæmoglobin concentration. Until further information is available it seems reasonable to regard patients with normal THb as healthy from the point of view of anæmia

But cases of "dilution anæmia" may not be diagnosed as such and may be treated as having genuine anæmia Because the "anæmia" is refractory to other treatment, these patients are sometimes given numerous blood-transfusions (as well as parenteral iron and liver or vitamin B_{12}) over long periods of time (see accompanying table) The purpose of this letter is to draw attention to these states in the hope that blood-transfusions, which are probably unnecessary in simple hypervolæmia, and which are expensive and not without danger, may be avoided.

A more thorough examination of dilution anæmias is in preparation.

SHOULD BIBLIOGRAPHIES GIVE TITLES OF PAPERS?

SIR,—The bibliography of American medical papers is much more valuable than that of British papers, because of the almost invariable American practice of giving titles Is it not time that we in this country adopted the American practice, and will not you, Sir, pioneer this advance?

The Middlesex Hospital,
London, W 1

DAVID H PATEY

*** We agree with Mr Patey that there are advantages in giving titles in references, but the extra space needed is, we think, too great to justify making this change in *The Lancet* Under our present system we use a weekly average of between one and two columns for references to original articles To include titles of papers would at least double this consumption To compensate for this, we should have to exclude an article of perhaps 1000–1200 words —ED L

PHYSICAL CHANGES IN THE PROLAPSED DISC

SIR,—Some of the questions raised in your annotation[1] are answered in work already published by us[2-10] This was recently summarised by us at the March meeting of the Comparative Medicine Section of the Royal Society of Medicine[10] To reiterate briefly the tendency to disc prolapse depends upon the intra-disc tension and the structural state of the annulus fibrosus and the nucleus pulposus

Increase of intra-disc tension possibly arises as a result of the "triggering" of a sequence of changes probably by an endocrine factor whereby, amongst other possible changes, depolymerisation of the polysaccharides of the nucleus leads to increased power of fluid absorption and thus increased fluid absorption with resultant rise in intra-disc pressure As the depolymerised molecules are removed there is a return to the status quo with relief of symptoms With each episode of symptoms, this process is repeated so that the total polysaccharide content is reduced, producing a degenerated, desiccated disc A stage will be ultimately reached whereby the concentration of the polysaccharide and power of fluid absorption are so reduced that prolapse cannot occur

Our intra-disc pressure measurements showed fluid absorption to produce the highest pressures in the 35–55 age-group, which parallels the incidence of disc prolapse Our X-ray crystallographic studies have shown that beyond the age of 40 the reduction of polysaccharide, though relative, is associated with precipitation of the collagen Such a process causes the incompressible gel structure of the nucleus pulposus to change to a fibrosed mass incapable of *uniform* transmission of stress This uneven dissipation of stress causes gradual attrition of the annulus With increasing age, precipitation of the collagen in the annulus results in decreased elasticity We

suggest that nuclear herniation becomes less frequent in the older age-groups partly because of these changes in the gel structure and function of the nucleus and partly because there is insufficient polysaccharide to develop an adequate intra-disc pressure

Answering Mr Charnley's question,[11] we think this outline of our views parallels the concepts described in his letter

Physics Department,
Institute of Advanced Technology,
Bradford D L SMARE

Textile Department,
Institute of Advanced Technology,
Bradford F HAPPEY

Royal Infirmary,
Bradford 9 A NAYLOR

SIR,—At the 1954 autumn meeting of the British Orthopædic Association when Mr Charnley introduced into a discussion his postulate of the hyperhydration of the nucleus, he prefaced it with the remark that this was "a little fairy tale which he liked to tell to his students" I thought that this terminology indicated a becoming but proper modesty—becoming because the idea could clearly be the source (which is always necessarily imaginative) of a new and valuable concept, and proper because a proved factual basis for the concept was lacking So far as I know no experimental or other confirmation has since appeared, but the postulate seems none the less to be in some danger of being elevated into a thesis

When I first began my investigations into disc behaviour six years ago, Mr Charnley's original observations had already been published, and I expected that some evidence of a "super-saturation" phenomenon would indeed come to light This did not prove to be so, but I do not think that the divergence between the two views is as complete as is being implied Some confusion may well arise from the (to my mind) incorrect use of the word "desiccation" A man who has been sitting with rubber boots on and with his socks fully but exactly saturated with water, and who then stands up, is unlikely to complain that his feet are desiccated, although he may, if of a dispassionate turn of mind, concede that his socks have become drier An inefficiently functioning nucleus, similarly, becomes "drier" under load, but the significance of this lies in the excess of fluid which is thereby liberated Our rubber-booted, wet-socked citizen becomes conscious of water-exchange on weight-bearing, our annulus in like manner suffers from the repeated appearance of abnormally large volumes of suddenly "unbound" tissue fluid Furthermore as the annulus loses its elasticity and the nucleus accordingly becomes almost completely unstressed with recumbency, the gel has to work on that part of its imbibition pressure-saturation curve where (the curve being exponential) a given increment in load is accompanied by the maximum change in saturation And all this in a cavity with two rigid walls and a strictly limited rate of fluid diffusion If these phenomena are inadequate to explain the eventual rupture of an already weakened annulus, then perhaps I should, in the best Scots manner, take to studying imbibition in another form

Mr Charnley cites the difficulty of explaining on this basis the attack of "lumbago" that lasts as long as three weeks I cannot say that I find such long-lived symptoms and signs common unless in patients who then or subsequently produce root signs But is there any reason for the pain's not lasting as long if the ruptured fibres of annulus happen to include a sizeable nerve-fibre? Or if a cartilage end-plate is damaged? Or if the pain threshold is low? Or is there any proof that the pathology is in fact then in the disc? Can this picture not appear with facetal joint strains, interspinous ligament tears, minor congenital abnormalities of dura or vertebræ, with the vicious circle of muscle spasm—pain—muscle spasm, or even perhaps—since fancy may apparently sometimes obtrude in discussions of fact—the incarceration of dephlogisticated air (notoriously obdurate of absorption as I understand) in a dural pocket?

The fact is, of course, that none of us can answer even the beginnings of all the questions in disc pathology We are entering a field of what could optimistically be described as new knowledge, but which is more realistically seen as fundamental ignorance The basic chemistry and the metabolism of the polysaccharides are closely involved, and are so far largely unknown It is clearly possible that Mr Charnley's postulate will subsequently find confirmation, and that the physical abnormalities I have found are of less significance than I think, or capable of different interpretation But in so difficult a field would we not do well, in the meantime, to avoid discussions based on conjecture, or on intuition, or on highly subjective considerations such as the character of the pain produced, and concern ourselves with such facts as have been demonstrated? There is already a reasonable basis of pathological physics to work on and a great mass of accurately observed anatomical change The next step should surely be to enlarge or to revise that basis by physical experiment or to investigate its chemical, and eventually its metabolic, background

Royal Infirmary, Aberdeen NEIL G C HENDRY

RECORDS OF IMMUNISATION

SIR,—I have read with interest the correspondence which started with Dr Randall's letter of May 3

In the Southern Gas Board we decided, in consultation with Dr H J Parish, of the Wellcome Research Laboratories, to offer active immunisation with tetanus toxoid on a voluntary basis to all men employed in our mains and service laying gangs

The records of the inoculations are entered on the cards provided by Messrs Burroughs Wellcome, and on completion of the third injection the card is given to the patient with instructions to carry it on him and, should he at any time be taken to hospital, to present the card to the doctor who treats him

There is on these cards plenty of room for the inclusion of details of any other immunising injections which the patient may receive

Medical Department,
Southern Gas Board, Southampton M B CARSON

TREATMENT OF NEPHROTIC NEPHRITIS WITH CHLOROQUINE

SIR,—We have observed a favourable effect of chloroquine on the nephritis component of systemic lupus erythematosus [1] According to Mellors [2] there is a similarity in the pathogenesis of the nephritis of lupus and that of the nephrotic type of chronic nephritis

Accordingly we have treated in this hospital three patients with the nephrotic type of chronic nephritis by bed rest, low-sodium diet, and chloroquine diphosphate in doses ranging from 0 75 g to 1 g daily for 2 to 4 months In each case the nephrotic syndrome has disappeared, with suppression of œdema, increased diuresis, and subsidence of hæmaturia Proteinuria fell from 3 2 g per litre to 0 25 g in the first patient, from 25 6 g to 0 20 g in the second, and from 34 7 g to 0 20 g in the third, during a period of 30 days α_2-globulin fraction and serum-cholesterol became normal and the total serum-protein level rose significantly

A control group of 26 patients with the nephrotic type of chronic nephritis were observed during 1 month in the same hospital, and were treated with bed rest and low-sodium intake In this group the variations in proteinuria, serum-cholesterol, and serum-protein were studied and their standard deviation determined The proteinuria varied from 6 49 g per litre to 7 58 g during the month The probability that the good results in the chloroquine group were due to chance is less than 1 in 10,000

INTESTINAL ANGINA

SIR,—Your leading article of June 7 is very informative and timely As former professor of internal medicine at the University of Vienna I feel I should draw attention to the fact that the late Prof Norbert Ortner was quite familiar with this disease and first described it in all its details long before it was "rediscovered" as a clinical entity One thing that prevented Ortner's syndrome from being generally recognised was probably his term "dyspragia intermittens angiosclerotica intestinalis" In my *Differential Diagnosis of Internal Diseases*[1] the clinical picture and its history has been briefly discussed

Los Angeles
JULIUS BAUER

RADIATION HAZARD IN ANTENATAL RADIOGRAPHY

SIR,—In the investigation of the hazards in diagnostic radiology the recent approach has been to study the histories of the children with leukæmia and other malignant conditions and in retrospect assess the exposure to radiation The series recorded here consists of all patients referred during the year *1948* for pelvimetry, and although the number is relatively small I feel the results are none the less significant

The year 1948 has been chosen to give a reasonable period for any harmful effect to become apparent in the children, and pelvimetry examinations have been selected in view of the high radiation dose involved. Information regarding the present wellbeing of the children has been obtained by kind cooperation of the health visitors, without whose help the follow-up would not have been possible, in view of the large population shift within and from Glasgow during recent years

The investigation covers 148 patients, all referred for pelvimetry to exclude pelvic contraction The average number of films per patient is 3, which is three times the present figure for the examination In 1 case, straight films for maturity and viability were taken, and 7 films were used, the largest single figure As the X-ray unit in use in 1948 is no longer available it is not possible to assess the dose-rates received The children of 104 of the 148 patients are alive and well, 21 are deceased due to causes listed below, and 23 have not been traced, some having emigrated Of the deceased there has been no report of leukæmia or other malignant condition

	No of deaths
Stillbirth	7
Pneumonia	4
Gastroenteritis	2
Accidents	2
Congenital abnormality	3
Unknown	1
Miscarriage	2

Since these children were submitted to a relatively high radiation dose compared with the present technique it is reassuring to know that as far as can be ascertained no case of leukæmia has been reported

I should like to thank Dr R McG C Crawford, consultant radiologist, for suggesting this investigation and for helpful advice The follow-up of the children's health would have been impossible without the active cooperation of Dr N I Wattie, principal medical officer for maternity and child welfare, and her health visitors

Southern General Hospital,
Glasgow

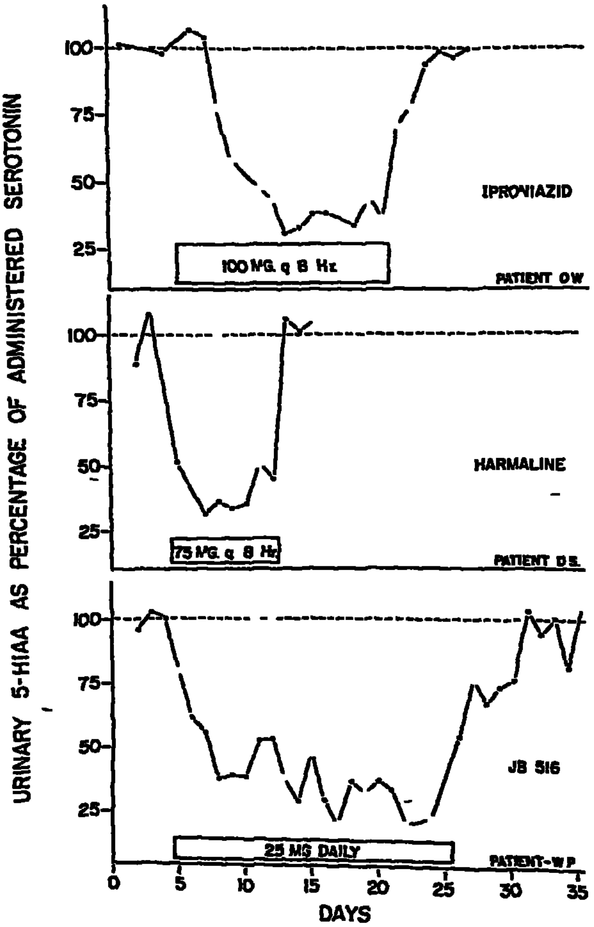
A SIMPLE METHOD FOR THE MEASUREMENT OF MONOAMINE-OXIDASE INHIBITION IN MAN

SIR,—There is currently much interest in the therapeutic potential of drugs which have been shown in animals to inhibit the enzyme, monoamine oxidase (M A O) The best-known of these agents, isopropyl-isonicotinyl hydrazine (iproniazid, 'Marsilid'), is being used in psychiatry in depressed patients, as well as in the treatment of two cardiovascular disorders, hypertension and angina pectoris[1] A pertinent question is whether these agents do inhibit M A O to a significant extent in man and, if so, whether the therapeutic effects are the results of the M A O inhibition To help answer these questions we have devised a simple test based on the conversion of orally administered serotonin to 5-hydroxyindolacetic acid (5-H I A A), the end-product of M.A O activity[2]

Following oral administration of an arbitrary dose of 20 mg of 5-hydroxytryptamine (serotonin), urine is collected for an 8-hour period and assayed for 5-H I A A[2] Repetition of this procedure on several successive days establishes a control range of conversion to 5-H I A A for a given patient, usually between 18 and 22 mg per 8 hours This procedure is con-



Effect of M.A.O inhibitors on conversion of serotonin to 5-H.I.A.A. in man tinued during the administration of a presumed M A O inhibitor

---

[1] Bauer, J Differential Diagnosis of Internal Diseases New York, 1955

[1] Symposium on Iproniazid *J clin exp Psychopathol* suppl, 1958, 19

[2] Udenfriend, S, Titus, E. O, Weissbach, H *J biol Chem* 1955, 216, 499

Although infusions of serotonin are poorly tolerated, the oral administration of serotonin should be of no concern since a common food item, the banana, contains considerable amounts of it [3] We have administered as much as 50 mg of serotonin orally to patients without any observable effects, even in the presence of M A O inhibitors During these studies the only effect observed was orthostatic hypotension, attributable to the M A O inhibitors themselves

The results obtained with three drugs are presented for illustrative purposes (see accompanying figure) They were administered on a regular schedule, stipulating only that a dose be given 2 hours preceding the administration of serotonin each day It is apparent that all three drugs markedly reduced the conversion of serotonin to 5-H I A A Iproniazid and (1-methyl-2 phenyl)-ethyl hydrazine hydrochloride (JB-516)* are examples of long-acting M A O inhibitors Harmaline, a harmala alkaloid recently shown to be a potent inhibitor of M A O in animals,[4] is an example of a short-acting inhibitor [5]

The reduction in the percentage of conversion of serotonin to 5-H I A A indicates that these agents do inhibit M A O in man, and that the inhibition may be quite marked From previous studies with animals it is known that all three drugs reach the target enzyme throughout the body [1,5,6] Diminution of 5-H I A A production by this test may therefore be taken as representative of an overall inhibition of M A O, although it presumably measures only the inhibition occurring in the gastrointestinal tract and probably in the liver

There is a widespread flurry of activity to uncover new compounds which will possess such inhibitory effects with a minimum of toxicity For these reasons we have devised this simple test, applicable to man, realising that further refinements in its application will be forthcoming and hoping that this type of procedure will place M A O-inhibition therapy on a rational basis It will also be interesting to determine whether there are disease states in which M A O activity is impaired

CLEAN BLANKETS

SIR,—Because the sterilisation of woollen blankets, while preserving their natural properties, appeared to be impossible, attempts were made to devise a substitute In view of the recent publicity in the Press this letter is written to inform your readers that a boilable bedcover with all the social properties of the conventional blanket is under trial It has been found to be warm and comfortable, is easy to launder, handles well, is durable, and is reasonably cheap Work is still in progress testing the effects of bactericidal chemicals and their carry-over after washing It would be premature at this stage to give further details, for the blankets are not yet available in commercial quantities

Nuffield Department of Surgery,
University of Oxford

J S CALNAN

SIR,—Your leader of May 17 draws attention to the part played by woollen blankets in spreading infection in hospitals It is now possible to obtain cotton blankets that give the same thermal insulation as wool at less weight and less expense They can be sterilised and laundered by the methods used for other cotton articles

This type of material was developed at the Shirley Institute, and was the subject of experiments on cross infection in hospitals reported by Blowers, Potter, and Wallace [1]

British Cotton Industry Research Association,
Shirley Institute, Didsbury,
Manchester

THE MEDICAL DIRECTORY

The Editor of *The Medical Directory* writes

"The annual schedule, upon the return of which the accuracy of *The Medical Directory* depends, has recently been posted to all traceable members of the medical profession, and its speedy return would be appreciated

"A number of schedules, sent to a doctor's last known address, have been returned through the post office marked 'Gone Away' Although in such cases every effort is made to find a new address, I should like to remind practitioners that if these efforts are not successful before the book goes to press, the names in question will be omitted from the next edition

"Any doctor who has not received the annual schedule, or who has mislaid it and would like a duplicate, is requested to communicate as soon as possible with The Editor, The Medical Directory, 104, Gloucester Place, London, W 1 The full name and year of qualification of the doctor should be sent for identification, please"

Parliament

Prevalence of Bronchitis

ON July 9, on the adjournment, the Rev LLWELYN WILLIAMS drew attention to the fact that Britain has the worst record in the world for bronchitis The death-rate was four times as high as that in the Ruhr or industrial Belgium, and about twenty times as high as that in the Scandinavian countries In nearly all other countries the death-rate had fallen since the end of the war, but in Britain the position was substantially the same as in 1940 despite the introduction of new and powerful drugs People often waxed indignant at the number of days lost through strikes, yet in 1956 industrial stoppages were responsible for the loss of 2 million working days while bronchitis was responsible for the loss of 25 million

QUESTION TIME

Security Precautions at Broadmoor

Mr MARCUS LIPTON asked the Minister of Health what action he would take to improve security precautions at Broadmoor —Mr WALKER-SMITH replied The Board of Control has decided to hold an inquiry into the recent incident at Broadmoor Institution, and I must await its report Mr LIPTON Will this inquiry be a full inquiry, in view of the widespread public misgivings caused by the recent escape? For example, will the inquiry take note of the unanimous view of the 230 male nurses in London, employed at Broadmoor, who have made urgent representations to the Minister that, from the security point of view, the Home Office should have some say in this matter?

Mr WALKER-SMITH This will be a full inquiry in the sense that it will inquire into all matters which are relevant and into which it is constitutionally proper for the Board of Control to inquire —Mr A R HURD Will this be an independent inquiry such as the Scott Henderson inquiry?—Mr WALKER-SMITH This will not be an independent inquiry in the sense of the Scott Henderson Committee I have already said that this is an inquiry by the Board of Control It is an inquiry into this specific incident which is the first serious escape since the publication of the Scott Henderson findings in 1952 The procedures were reviewed by the Scott Henderson Committee This is obviously a more narrow approach

---

* Synthesised and supplied by Lakeside Laboratories, Milwaukee, Wisconsin

[6] Spector, S, Prockop, D, Shore, P A Brodie, B B *Science*, 1958, 127, 704

[1] *Lancet*, 1957, i, 629

Mr R. T. PAGET Will the Minister bear in mind the remarkable achievements in curing people by Broadmoor and not be panicked by this sort of thing into making medical treatment in Broadmoor impossible?—Mr WALKER-SMITH I have in mind these considerations as well as the conditions of security.

Shortage of Nurses

Mr P. C. GOODHART asked the Minister how many beds in mental-deficiency units were out of commission in the South-East Metropolitan Regional Hospital Board area because of shortage of nursing staff. Mr WALKER-SMITH replied 230.

Mr GOODHART Is the Minister aware that the number of beds standing empty because of shortage of staff is nearly equal to the number of mental patients awaiting entrance to these units in this area?

Royal Commission on Remuneration

Mr KENNETH ROBINSON asked the Minister whether the Royal Commission on Doctors' and Dentists' Remuneration had finished taking evidence, and when he expected to receive its report. Mr WALKER-SMITH replied The process of taking evidence and collecting necessary information will not be completed for some months, and, while the Commission intends to submit its report as quickly as possible thereafter, it does not expect to be able to do so until next year.

W.H.O. Malaria Fund

Mr ARTHUR BLENKINSOP asked the Minister whether he would make a contribution to the World Health Organisation's malaria fund.—Mr RICHARD THOMPSON, the parliamentary secretary to the Ministry, replied It is not possible in present circumstances to supplement the contributions which we make to the regular budget of the World Health Organisation. We are in any case already making substantial contributions in this field. Mr BLENKINSOP Before the parliamentary secretary turns this down altogether, may I ask him to ask the Minister and the Chancellor of the Exchequer to look at the implications of this matter again, in view of the very high scientific advice which is available that this is a most urgent world problem and that we stand to gain from its solution as well as everybody else in the world?—Mr THOMPSON Yes, but we are opposed to the creation of special funds financed by voluntary contributions for organisations which are normally financed by compulsory assessment on member States.

Health Centres

Since the start of the National Health Service, local health authorities have established 9 health centres. 3 are under construction, and another will be started this year. 9 other schemes have been proposed, and 3 at least of these are likely to be started in 1959-60.

Mental Health Services

In the last financial year about 11½% of the total cost (about £585 million) of the National Health Service is identifiable as having been spent on mental health services. This includes 11% by hospitals (about 19¼% of their expenditure) and ½% by local health authorities (about 5½% of their expenditure). Certain administrative expenses of hospital authorities, which cannot readily be identified with individual hospitals, and the cost of beds for mental illness in acute hospitals, which cannot be separately ascertained, are not included. Similarly local health authorities incur some additional expenditure on mental health which is not separable from that on their other services.

Carbromal and Bromvaletone

The Poisons Board, at its meeting on June 18, decided that the evidence before it was insufficient to warrant any change in its recommendation of 1955 that preparations containing carbromal, or carbromal and bromvaletone, should not be controlled under the Poisons Act. The Home Secretary has accepted this recommendation. The Minister of Health proposes, however, at the suggestion of the Board, to invite the committee on drug addiction, recently set up under the chairmanship of Sir Russell Brain, to examine further the risks attending the abuse of such preparations.

Obituary

ISIDOR CLINTON RUBIN

M.D. Columbia

SOME of the finest ambassadors have no ambassadorial rank, and Dr Rubin, the distinguished American gynæcologist, who died in London on July 10, was a member of this small band of world citizens, for by his vision, warm sympathy, gentle culture, and manner of living he denied the artificial bounds of race, colour, and political dogma.

He studied medicine in New York and became an M.D. of Columbia University in 1905. He worked at Mount Sinai Hospital from 1905 to 1909 with Dr H. N. Vineberg, who advised him in 1909 to go to Vienna for further study. There Rubin came under the influence of Professor Schottlander, pathologist to the University Frauenklinik, who introduced him to laboratory methods of scientific work and helped him to prepare his first papers. In 1910, on his return to the United States, Rubin was appointed gynæcologist at the Beth Israel Hospital, and in 1929 he became director of the gynæcological service there. From 1937 to 1947 he was clinical professor of gynæcology at Columbia University, and from 1948 clinical professor of obstetrics and gynæcology at New York University.

He was honoured in many countries. In 1955 he was made an officer of the French Legion of Honour, and the Royal College of Obstetricians and Gynæcologists of Great Britain made him an honorary fellow in 1957. He was a familiar figure at congresses all over the world, and he was a welcome visitor to the last British Congress of Obstetrics and Gynæcology, held at Oxford in 1955.

Rubin will perhaps be best remembered for his work on tubal insufflation, of which J. A. S. writes:

It was in 1914 while he was working in the laboratory of Wertheim at Vienna that Dr Rubin first became interested in the demonstration of the uterus and tubes by radiological methods. He injected 'Collargol' into the postmortem human uterus and into the uterus of living rabbits. He was quick to realise the possibility of diagnosing submucous fibroids by this technique and he saw that with this new method it would be possible to demonstrate tubal patency in the living by the use of radio-opaque solutions. Collargol was not adopted in practice because of toxic side-effects, but later, when 'Lipiodol' was developed, the technique of hysterography and salpingography became a routine procedure in fertility testing. Rubin then realised the possibility of using gas to demonstrate tubal patency, and in 1919 at Mount Sinai Hospital in New York he performed his first uterotubal insufflation. His many subsequent papers chronicle the developments and improvements of this technique, the carefully laid-down criteria for its safe performance, and analyse critically the results achieved. His interest in this problem was much deeper than many have appreciated, for he was not engaged in merely demonstrating tubal patency. He was interested above all in function. His work threw much light on tubal function from anatomical, physiological, pharmacological, and clinical points of view. He demonstrated the relation between tubal function and the hormonal factors of the menstrual cycle. He tested and recorded the pharmacodynamic influence of various drugs on the uterus and tubes. However encouraging the results, Rubin was always searching for something better, and until the day of his death he was still investigating the ideal radio-opaque medium for use in radiological investigations of the genital tract.

His published papers show the breadth of his interest. Like Bonney, he was a firm believer in conservative techniques when these could be employed without hazard to the patient. He was an advocate of myomectomy instead of hysterectomy during the childbearing years He was keenly interested in the problems of pelvic pain, dysfunction due to autonomic factors, and the influence of hormones on the genital tract, and in the importance of gynæcological pathology He has been justly described as a prolific writer More important, however, is the fact that his contributions were all examples of clear thought and concise expression His collected papers, from 1910 to 1954, were published privately in 1954, and those who have read the collection will have been impressed by the generous tributes paid to him in the three forewords by distinguished colleagues from three different countries Dr Emil Novak from Johns Hopkins, Dr Axel Westman from Stockholm, and Dr Bernard Zondek from Israel, all wrote simply and sincerely of his high scientific integrity, of his modesty, of his profound culture and noble character, and of those social graces which made him such a delightful companion

Dr, Rubin was an outstanding surgeon and a great man much beloved We mourn his passing but are grateful for his life and work

CYRIL JOHN MORGAN

M B , B Sc Wales, D P M

Dr Morgan, consultant psychiatrist and medical superintendent of Morgannwg Hospital, Bridgend, Glamorgan, died on June 26 at the age of 42

He was born at Penydarren, Merthyr Tydfil, Glamorgan, and he was educated at Cyfarthfa Grammar School, Merthyr, and at the Welsh National School of Medicine in Cardiff, where he graduated B SC in 1936 and M B in 1939 After holding a resident appointment at Pontypool Hospital he joined the R A M C , and served as a psychiatrist in this country and in West Africa until he was demobilised in 1945 The same year he joined the staff of the Rainhill Hospital, Liverpool, where he became senior medical officer He took the D P M in 1947, and in 1949 he was appointed deputy medical superintendent at Morgannwg Hospital, Bridgend He became medical superintendent four years ago He leaves a widow and three young sons

M D A writes.

Cyril Morgan was a truly dynamic personality, and he will ever live in the memory of all who knew him for his innate kindliness, his ever ready help, his seemingly tireless energy, and his infectious enthusiasm He was a brilliant and stimulating conversationalist, and had an exceedingly wide range of interests

ANDREW MEARNS FRASER

M D Edin , D P H

Dr Mearns Fraser, who was medical officer of health for Portsmouth from 1896 to 1934, died on July 8 in the Royal Portsmouth Hospital at the age of 90 To the older generation of public-health doctors his name will bring back memories of a man of outstanding ability and great personal charm

He was born at Reading and educated at the City of London School and at the University of Edinburgh, where he graduated M B in 1893 Two years later he took the D P H and joined the staff of the Essex County Council as assistant M O H , and he held this post until he moved to Portsmouth in 1896

H C M W writes

During the expansion of the health services in the early part of the century Mearns Fraser was one of the pioneers in the development of the tuberculosis service, and he established one of the first of the tuberculosis dispensaries, which was known in Portsmouth as the "tuberculin dispensary" After the 1914–18 war he took an active part in the campaign to check the dissemination of venereal diseases At that time he met with a great deal of opposition in his advocacy of the use of potassium permanganate as a prophylactic because it was thought that this would lead to promiscuity Apart from organising efficient local clinics and other services he supported many national bodies associated with preventive medicine He was a member of the council of the Society of Medical Officers of Health, of the departmental committee set up by the Local Government Board in 1912 on the future national policy to combat tuberculosis, and of the departmental cancer committee

When he retired in 1934 the regard and affection in which he was held by his staff and the people of Portsmouth was shown by the many tributes and presentations made to him. He retired to Hayling Island close to the golf course, so that he might enjoy to the full his well-earned years of retirement in a place that offered all the facilities for his favourite recreation. His many friends were delighted that he was still playing up to two to three years ago

Dr Mearns Fraser leaves a widow and two daughters

Sir ARNOLD STOTT

H S C S , who with Stott was one of a trio who worked and played together from their last years at Cambridge till the end of their house-appointments at Barts, writes

Arnold was really very consistent once it was grasped that his true period was the late 18th or early 19th century, when society was still essentially aristocratic Medicine he made his chief and therefore very successful hobby, but he might have been equally outstanding in the cotton world of Manchester, and probably ended his career as lord lieutenant of the county He was the most generous and kindhearted of men, but simple little remarks, really thinking aloud and uttered in his cool deliberate voice, which were the delight of his friends, sometimes had a devastating effect on those who only knew him slightly At our last meeting at the Fountain Club shortly before his retirement, which we were discussing, he remarked suddenly, " One thing really distresses me People so often seem afraid of me Why is it ?" and it was a great shock to think that perhaps with his seniority that could be possible though well-nigh incredible

By his transfer from Barts to Westminster the latter hospital had the great good fortune to acquire one of the last of the " vintage " physicians

Appointments

CAIRNS, J G , M B Glasg , D P H M O H , Halifax

CAPSTICK, A L , M B , B SC Wales, D P M assistant psychiatrist (S H M O), Whitchurch Hospital, near Cardiff

DONOVAN, J F , M R C S , D P M medical superintendent, St Lawrence's Hospital, Bodmin, Cornwall

GARFIT CLOWES, LOUISE M E , M B Belf , D P H assistant M O , Surrey

LATHAM, ALICE, M B , B SC Wales, D OBST , D C H assistant M O , Surrey

ROBERTS, T E , M B Lond , D OBST , D P H deputy M O H , High Wycombe and Marlow, and assistant M O and school M O , Buckinghamshire

SPARROW, OLIVE M , M D Lond assistant M O , Haltemprice, near Hull

SPENCER, S J G , D M Oxon , D P M consultant psychiatrist, Digby Wonford Hospital, Exeter

ZALIN, HAROLD, M B Lpool, F R C S E , D L O part-time consultant E N T surgeon, Walton Hospital, Liverpool

The Hospital for Sick Children, Great Ormond Street, London:

CORLETT, KEITHA, M B , N Z , M R C P , D C H house physician

LEADER, LESLEY P , M B , B SC Lond , M R C P house physician

MUNRO, A I , M B Lond house surgeon

WESTON, H J , M B N Z , M R C P , D C H resident assistant physician

WILSON, P E , L R C P I , D P H assistant medical registrar

Newcastle Regional Hospital Board:

DAYAN, ELIA, M B Cairo, F R C S senior casualty officer, South Shields group of hospitals

DUTTON, J E M , M B Durh , F R C S consultant neurosurgeon, Sunderland hospital group and regional neurosurgical service

HENDERSON, C B , M D Durh , M R C P consultant cardiologist, regional cardiovascular unit, Newcastle General Hospital, and regional thoracic surgery centre, Shotley Bridge General Hospital

ISMAY, GEOFFREY, M D Durh , M R C P consultant general physician, south west Durham and Durham hospital groups

MARSHALL, MERLIN, M B Cantab F F A R C S consultant anæsthetist, Newcastle upon Tyne hospital group

NEAL, F E , M B Sheff , D M R T assistant radiotherapist (S H M O), regional radiotherapy service

WELCH, R G , M D Lond , M R C P consultant pædiatrician, Hartlepools and Tees side hospital groups

Notes and News

WORK OF THE KING'S FUND

At the sixty-first annual meeting of King Edward's Hospital Fund for London on July 10, the Duke of Gloucester, the president, said that the Fund's grants had provided improvements of many kinds Very many hospitals showed the results of the Fund's grants to provide better living conditions for the nurses To build a recreation hall was often too large an item to be met by any other means than a grant from the King's Fund, and the Fund had now given a number of such halls, as well as making many improvements in nurses' homes At present there was a great need in some hospitals for better arrangements for the increasing number of staff who were non-resident, and the Fund had made grants to provide changing-rooms and sitting-rooms for them The Duke referred to the great difference that might be made to the quality of the future hospital service by various training schemes financed by the Fund The work of the three staff colleges—for ward sisters, for hospital administrators, and for future matrons—as well as the School of Hospital Catering, had led to results which were no less real

Lord Ashburton, the treasurer, moving the adoption of the accounts, said that last year for the first time the Fund's income had exceeded £400,000 This included a further instalment of £50,000 from the Nuffield Trust for the Special Areas In all the King's Fund had distributed more than £16 million to the hospitals of London, and still held a capital of over £7 million

INSTITUTE OF MEDICAL LABORATORY TECHNOLOGY

For the fourth time in fifteen years, this institute has moved to larger premises because of the growth in its membership and commitments Its new headquarters at 74, New Cavendish Street, Harley Street, London, W 1, were acquired at the end of last year and were occupied in May At the house-warming on July 2, Prof E T C Spooner, the president, received many pathologists who are honorary fellows of the institute, in addition to several past and present officers and others closely associated with its work

The voluntary Association which was the forerunner of the present institute took some thirty years to reach a total of 1000 members, which was its strength when the institute was incorporated in 1942 The increase to nearly 7000 members today is an indication of the expansion of the pathology services

---

University of Oxford

On June 26 the following degrees were conferred

D M—S J G Spencer
B M—Colin Bell (in absentia)

University of Cambridge

On June 25 the degree of B CHIR was conferred on the following

University of Birmingham

On July 4 Prof A Lacassagne, of the Pasteur Institute in Paris, opened clinical research laboratories at the Medical School The laboratories, which have cost £50,000, were provided by the Birmingham branch of the British Empire Cancer Campaign

They are situated on the site reserved for clinical research near the Queen Elizabeth Hospital and the Medical School at Edgbaston The laboratories will permit all cancer research in Birmingham to be centred in one place Dr John Orr, professor of pathology in the university and director of cancer research, has been closely concerned with the project After Professor Lacassagne had declared the laboratories open, Prof L Severi, of the University of Perugia, unveiled a plaque commemorating the work of Sir Gilbert Barling, the first chairman of the Birmingham branch of the British Empire Cancer Campaign A second plaque, commemorating a gift of £30,000 from Alfred and Ruth Bullock towards the cost of the laboratories, was unveiled by Dr O Muhlbock of the Dutch Cancer Institute, Amsterdam

University of Durham

On July 4 and 5 the following degrees and diplomas were conferred

M D—G S Anderson, *Gordon Pringle, *G A Stirling
M B, B S—John Anderson, W V Anderson, Margaret S Atkins, Judith C H Bullen, Margaret S Burrill, Mary Bynon, *P M Calamel, I G Campbell, John Cape, Jean Carr, Ben-Zion Chalk, J R Cox, W G Donald, C M Dunn, L E Dunn, Elizabeth Elliott, M A Ferri, Gerald Gill, C P Gillie, H L Goldwater, Ronald Heslop, D H Irvine, Fiona M Lehmann, Margaret A Lewis, Thomas Lind, J B McCafferty, A J McComas, C H McCulloch, Alastair Malcolm, P F Moran, J M Morrison, H N Murray, Harald Natvig, Sarah H J Nelson, S A Oduntan, I, L T Oluwole, Alan Poweny, D G Proudler, D N Raine, Donald Rankin, M F Reece, Ernest Ross, Dorothy A Stevenson, J R C Stubbs, Margaret A Stubbs, Ernest Taylor, I H Taylor, Stanley Tetlow, Jean B Thompson, P R Uldall, Michael Ward, Joan M Whitmore, P G Wood, P H Yorke

University of Liverpool

Dr W E Kershaw has been appointed to the Walter Myers and Everett Dutton chair of parasitology and entomology, on the retirement of Prof R M Gordon

Dr Kershaw, who is 47 years of age, graduated M B from the University of Manchester in 1935, and four years later was awarded a junior research fellowship in tropical medicine with the Medical Research Council During the late war he served with the R N V R at sea and later as pathologist to the Royal Naval Auxiliary Hospital in Ceylon In 1946 he was appointed lecturer in medical parasitology in the Liverpool School of Tropical Medicine In 1949 he took the degree of M D with commendation He was awarded the Chalmers medal of the Royal Society of Tropical Medicine and Hygiene in 1955, and the following year graduated D SC Last year he was appointed Leverhulme senior lecturer in parasitology at the school He has made annual visits to the Cameroons and Nigeria for some years in connection with the helminthiasis research scheme of the Colonial Medical Research Council, and he represented the school at the World Health Organisation conference on onchocerciasis at Leopoldville in 1954

University of Glasgow

On June 18, the D P H was awarded to the following

R E Atkinson, D B Campbell W MacD Campbell, A J Childs, Margaret J Devine, D E Donald, Margaret E Forbes, G S Henderson, A S L Kennedy, J E Lunn, Marion T Lunn, Archibald McCutchion, Sheila Macintyre, J B Morris, W M Prentice, Frank Slane, A McI Tait

National University of Ireland

Dr D K O'Donovan has been appointed to a senior professorship of medicine and Mr Patrick Fitzgerald to a senior professorship of surgery at University College, Dublin

Royal College of Surgeons of England

At a meeting of the council held on July 10 Sir James Paterson Ross was re-elected president of the college Sir Archibald McIndoe was re-elected, and Mr A Dickson Wright was elected, vice-president Dr Warren H Cole, of Chicago, and Dr Charles W Mayo, of Minnesota, were admitted as honorary fellows Dr H J Windsor, of Brisbane, was admitted to the fellowship, as a member of 20 years' standing A diploma of fellowship was granted to R M Wagh

Dr Geoffrey Organe was coopted to the council as a representative of anæsthetics Dr Ivan Magill, Dr R J Minnitt, Dr E S Rowbotham, Sir Henry Souttar, and Dr R M Waters were elected honorary fellows in the Faculty of Anæsthetists

The following lecturers were elected for the coming year

Hunterian professors —W E Tucker, traumatic syndrome phases and stages, R A Mogg, congenital anomalies of the urinary tract, E M Nanson, tumours of the parotid gland, J B Curtis, subarachnoid hæmorrhage and intracranial aneurysms, C J Kaplan, conservative therapy in skeletal tuberculosis, P H Jones, lobectomy and bronchial anastomosis in the surgery of bronchial carcinoma, G J -Hadfield, hormone deprivation in breast cancer, A G Parks, microanatomy of the breast, T J S Patterson, congenital deformities of the hand, J W Dickson, pathological ossification in nervous disease, Cyril Harvard, non-malignant bile-duct obstruction, A J Davies, carcinoid tumours, G S M Botha, the closing mechanism between stomach and œsophagus and its importance in surgery of the gastroœsophageal junction, J S Calnan, surgical treatment of speech disorders

Arris and Gale lecturers —E R Smith, anatomy and physiology of the bile and pancreatic ducts, G L Bourne, anatomy, physiology, and pathology of the human amnion and chorionic membranes, K M Backhouse, the gubernaculum testis Hunteri, testicular descent, and maldescent

Erasmus Wilson demonstrators —Richard Goodbody, K M Laurence, L W Proger, R C B Pugh, H A Sissons, M A Skelton

Arnott demonstrators —Jessie Dobson, A A Barton, Alan Howe, R J Last, R M Livingston, Bertie Cohen

Buckston Browne dinner —At this dinner on July 9 the toast of The College was proposed by Mr Derek Walker-Smith, Minister of Health, who laid stress on the importance of a positive approach to the health and wellbeing of the nation and especially the industrial population, as a means of improving the general standard of life Sir James Paterson Ross, the president, emphasised in his reply that research has a direct application to the practice of medicine and the alleviation of disease, it is like a tree with many branches Sir Archibald McIndoe welcomed The Guests, among whom were many leaders of the medical and industrial worlds Responding, Sir Harry Jephcott spoke of the college's worldwide reputation and of its valuable contribution to public as well as medical work

Royal College of Physicians of Ireland

On July 4 the following were admitted to the licentiateship of the college

J A Aziz, G O Balogun G A Bharmal, N P Boyle, D C P Brown, J J V Caraher, F B A Coker, D P Connolly, Josephine P Cummins, D A F Doherty, J F Doyle, P A Egbe, M J Fennell, J G A Fitzgerald, Eithne M A Flood, Gabriel Blankson-Hemans, J T Hogan, Mary C Horgan, O G L Hunter, J H Jackson, A M Jeeva, Mary J Keating, Mary P R Kenny, N M N Lamki, Trevor Morgan, Jack Mullins, J F X McGlade, Ina L McGregor, Peter McLean, P R P Naidu, B R O B Nation, M J Noronha, Catherine O Connor, Eamon O Daly, C M Omarjee, R J Osborne, Mary Owens, Richard Quirke, S D Ram, D F Reynolds, Dolly T Salami, S K Suleman, Dzintars Svenne, J B Swan, W H Twedell, T R Vij, P B Vilain, F G Walls, L A G Wharton, L R L Whitelocke, T A Worth, Paul Zamick

Society of Medical Officers of Health

Scottish Branch —Dr I A G MacQueen has been elected president

Chartered Society of Physiotherapy

This society will hold its annual conference at Bristol from Sept 11 to 13 The society welcomes doctors to any of the lectures, and complimentary tickets may be had from the registration secretary, physiotherapy department, Bristol Royal Infirmary

Fellowships at the University of Rochester

Buswell fellowships are offered to medical graduates for research in any department of the school of medicine and dentistry Graduates of British medical schools are eligible.

Junior fellowships will be awarded to medical graduates who have completed at least one year of internship or equivalent training Research experience is not required but will be of advantage, since fellows are expected to spend about 90% of their time in research or in advanced study in preparation for research They provide a basic stipend of $4500 to $6000 a year and may be renewed with increments for a second or third year An additional $350 a year may be provided for each dependent

Senior fellowships will be awarded to medical graduates who have held a junior fellowship for two or three years or have had comparable experience in medical research and wish to continue in an academic career They will provide a basic stipend of $5500 to $8000 a year, with provision for annual increments and dependants

Applications will be received at any time, and forms may be had from Dr L E Young, University of Rochester Medical Center, 260, Crittenden Boulevard, Rochester 20, New York

College of General Practitioners

Public Welfare Foundation Prize Competition 1958 —The college will award six prizes of £40 in a competition open to senior students of all medical schools in the United Kingdom and Eire The closing date for entries is Aug 1, and application forms may be had from deans of medical schools or from the college, 41, Cadogan Gardens, London, S W 3

Postgraduate Medical School of London

A symposium, for consultant physicians, on rheumatic fever and rheumatic heart-disease will be held from Sept 22 to 25 at the school, Ducane Road, W 12, and at the Canadian Red Cross Memorial Hospital, Taplow, Bucks The fee for the course is £4 4*s* and applications should be made by Aug 14 to the dean of the school

International Congress of Leprology

This congress, which was to have been held in New Delhi, is now to meet in Tokyo on Nov 12 under the sponsorship of the Japanese Leprosy Foundation and the International Leprosy Association The secretary of the association (8, Portman Street, London, W 1) asks all who will be able to attend the congress in its new location to let him know at once

Rochampton Courses on Artificial Limbs

The next courses on artificial limbs and rehabilitation after amputation for orthopædic surgeons will be from Oct 13 to 17 inclusive, and the next for specialists in physical medicine on Oct 29 and 30 Those interested should apply to the Principal Medical Officer, Artificial Limbs and Appliances Centre, Roehampton House, London, S W 15

Diary of the Week

JULY 20 TO 26

Tuesday, 22nd

SOCIETY FOR THE STUDY OF ADDICTION
8 P M (11, Chandos Street, W 1) Mijnheer H J Krauweel (Amsterdam) Incidence and Treatment of Alcoholism in the Netherlands

Wednesday, 23rd

The Lancet · Saturday 26 July 1958

CHILDREN IN HOSPITAL *

R S ILLINGWORTH
M D Leeds, F R C P , D P H , D C H
PROFESSOR OF CHILD HEALTH IN THE UNIVERSITY OF SHEFFIELD

SINCE Bakwin (1942) wrote on the loneliness of children nd Edelston (1943) on the results of separating them om their parents, much has been said about the psychogical effect of admitting them to hospital Among nportant papers are those of Powers (1948), Bowlby 1951), Jackson et al (1952), Prugh et al (1953), Capes 1955), Ylppo et al (1956), and Gofman et al (1957)

Exaggeration of Effects

On one hand, there is a tendency in some quarters to xaggerate the psychological trauma Prugh et al (1953), or instance, wrote that " most of the children showed daptive difficulties which persisted for weeks or months fter". I agree with Bowlby et al (1956) who, after a arefully controlled study of 60 children under 4 years of age spending a long period in a sanatorium, concluded that " Some of the workers who first drew attention to the dangers of maternal deprivation resulting from separation have tended on occasion to overstate their case In particular, statements implying that children who experience institutionalisation and similar forms of severe privation and deprivation in early life commonly develop psychopathic or affectionless characters are incorrect "

If this is true of long-continued institutional care, it is much more likely to be true of a short stay in hospital Exaggeration of the risk of harm can cause much unnecessary anxiety in parents and even delay necessary hospital treatment It can also lead other people to minimise this risk or even deny its existence

At the Children's Hospital, Sheffield, we follow up all children who have been discharged from the medical wards, in my experience it is exceptional for a child, on return home, to show behaviour problems which can be directly ascribed to his stay and experiences in hospital The only examples of severe persistent behaviour problems which I have been sure resulted from psychological trauma in hospital were in children who had been in long-stay orthopædic hospitals or infectious-diseases hospitals, in which no visiting was allowed

It is, of course, true that children cry in hospital Illingworth and Holt (1955) found that the majority of young children cry when their parents leave at the end of visiting-time, and that the majority show some emotional disturbance while in hospital, but that is quite different from suggesting that the experience of hospital commonly leads to behaviour problems which persist for weeks or months after discharge

Minimisation of Effects

On the other hand, some people tend to minimise the psychological trauma This tendency is seen especially among those who oppose daily visiting of children in hospital

Some time ago I set the following question in a pædiatric examination paper for nurses " Discuss the causes of crying in children in hospital " I was told that this was a most unfair question to set, because nurses had no experience of the problem, " for children do not cry in children's wards" I have heard it said that Robertson's film *A Two-year-old Goes to Hospital* gives an entirely untrue idea of what happens in a children's ward and is a gross exaggeration of the truth—a view with which I disagree

It would be indeed surprising if small children were not upset by admission to hospital They are particularly firmly attached to their parents in the first three or four years, and at no time do they feel the need of their parents' comforting love more than when they are feeling poorly It is unfortunate that it is just at this time that they are liable to be separated from their parents by admission to hospital Anyone, furthermore, is less adaptable when ill.

I imagine that every pædiatrician has seen behaviour problems which seemed to be directly ascribable to a period in hospital, and no-one could fail to observe the fretting and misery shown by some small children in hospital The problem of psychological trauma to children is real, and the fact that only a small minority show any ill effects after discharge must not lead us to minimise it Obviously we ought to do all we can to reduce such trauma, and to make the children's stay a happy one

Nature of Reactions

Short-stay Hospitals

At all ages, some children seem to be quite unaffected by admission to hospital they settle immediately and seem to be perfectly happy With young children, however, this is exceptional, the following reactions are commonly seen

(1) Persistent or frequent crying, and calling out for the mother Crying on departure of the parents after visiting-time

(2) Subdued and abnormally quiet behaviour in a child normally boisterous and happy

(3) Subdued and quiet behaviour until an attendant, doctor, or nurse approaches, when crying starts

(4) Subdued and quiet behaviour until the parents come, when crying starts

(5) Poor appetite, and in infants a failure to gain weight, despite absence of causal disease

(6) The development of enuresis or aggressiveness, mostly after a fairly prolonged stay

It is difficult to say with certainty what the child is thinking One feels that some small children are not altogether convinced that their stay in hospital is only temporary, and foolish statements to a child that he will " go home tomorrow ", when that is quite untrue, are bound to make him more and more sure that he is being left permanently in hospital I remember as a student being asked pitifully by a small boy " Doctor, when will it be tomorrow ? " He had been told repeatedly that he would go home tomorrow, but because of his illness (osteitis in pre-penicillin days) tomorrow was a very long time in coming

Long-stay Hospitals

The symptoms resulting from long separation from parents in the first three or four years have been adequately described by Bowlby (1951) and Robertson and Bowlby (1952) In an institution the predominant ones are quiet subdued behaviour and lack of spontaneous play and gaiety These children are " too good ".

I shall never forget a visit to a home for illegitimate children in a foreign city In a first-floor room were 20 or 30 children, aged 1 to 4 years, sitting on the floor like Madame Tussaud's figures they were quite still and were not laughing, crying, or talking There was no furniture in the room, apart from cots with solid wood sides which prevented the children in them from seeing out There were no toys On floor level there was an open french window, with nothing to prevent a child from falling out on to the concrete path below, but when a psychiatric friend of mine and I exclaimed about this, we were told that no child ever had fallen out We doubted whether one ever would the effects of emotional deprivation were so gross that the children did not move

---

* A lecture given to the Central Council for Health Education, Jan 23, 1958

There have been several papers about behaviour problems in children on return home from hospital The symptoms include regression to infantile behaviour, such as enuresis and excessive clinging, fear reactions, including night terrors, and negativistic reactions and signs of insecurity, such as temper tantrums, speech disturbances, and destructiveness

The late psychological effects of a long stay in hospital have been amply discussed by Bowlby (1951)

Ætiology

A big difficulty in considering this subject is to know how much of the crying or abnormal behaviour observed should be ascribed to the hospital experience and how much to the parents

Parental factors which may lead to or aggravate psychological trauma in children are

(1) Any disturbance of the parent-child relationship before admission or after discharge from hospital There is no doubt that the better this relationship and the more secure the child, the less likely is he to be significantly disturbed by a spell in hospital Before ascribing his crying in hospital and other bad behaviour to the trauma of his hospital experience, one needs to know what the child is like at home, and how he behaves there

(2) Lack of preparation or inadequate preparation of a child for admission when he is old enough to understand

(3) *Unwise or excessive preparation* by the parents as a result of anxiety about the effects of admission, and transference of parental anxiety to the child

(4) Threats made by the parents that if the child does not do what he is told he will no longer be loved, will be changed for another child, will be taken to the doctor, or, worse still, taken to the hospital and left there

(5) Lack of daily visiting by the parents when visiting is allowed This will be referred to later

(6) Transference of parental anxiety to the child during a visit Unwise remarks and promises by the parents during visiting-time which cannot be kept—e g, concerning the day of returning home

(7) Parental attitudes on discharge of the child These include spoiling the child, with overindulgence and indiscipline, especially when he has recovered from a dangerous illness

Apart from this, it is very hard to decide whether behaviour problems are due to the hospital experience or not In the first place, all children have behaviour problems, and the fact that a problem develops after a spell in hospital does not prove that it is due to the stay in hospital Secondly, it is easy to ascribe bedwetting after discharge from hospital to psychological trauma, when in fact it is due to failure of the nurses to attend to the child's toilet needs In hospital it is easy to have wet nappies and sheets washed, and this, combined with a shortage of nurses, may lead to neglect of a child's toilet needs Thirdly, as Ylppo *et al* (1956) point out, parents who have been pleased with the recovery of a child in hospital are not so likely to blame the hospital for a child's bad behaviour as are parents who have been in some way dissatisfied, or have disliked a ward sister, or have had other complaints It is very difficult to arrive at the

Lastly, children may have been alarmed, before by foolish remarks by their school friends, who provided them with lurid and totally incorrect of operations

We may summarise the relevant factors thus

(1) The age of the child The younger he is the greate the risk of psychological trauma

(2) The length of his stay in hospital The shorter the st the less likely is he to suffer any lasting psychological harm

(3) The *parent-child relationship at home*

(4) The nature of the experiences in hospital

(5) The nature of the illness (The significance of this uncertain)

(6) The personality of the child This very important fac is apt to be forgotten It is easy to ascribe a child's undesir behaviour to mismanagement at home when in fact it is due due to inherited personality characteristics Whether h personality depends on hereditary or environmental facto it is almost bound to have a bearing on his response to h experiences in hospital

(7) The preparation of the child for hospital and the attitu of the parents on his discharge

Beneficial Effect of Admission to Hospital

Of the many papers on the effects of hospital children, hardly any mention the psychological advantage Yet there is no doubt that many children benefit fro their experiences They profit from the companionsh of others, from the making of new friends, from the wi guidance of doctors and nurses (especially if they ha some disturbance of behaviour before admission), an from the learning of independence Ylppo et al (195 carefully observed 50 children under the age of 7 wh were admitted for minor operations They found th adverse changes after discharge were exceptional, an that behaviour improved in many Some were mor "irritable" after discharge than they had been befor admission, but an equal number were less so Ylpp et al remark that "the favourable effect of the hospital isation in the social behaviour of many children deserve special attention"

Prevention of Psychological Trauma

AVOIDANCE OF UNNECESSARY ADMISSIONS

The more efficient an outpatient department the fewe children will be admitted to the wards from it Ther are few special investigations which cannot be done i the outpatient department, though some children ma have to be admitted simply because they live a long wa from the hospital In my experience it is only rarel necessary to admit a child "for observation" or "fo assessment"—e g, for behaviour problems, menta deficiency, and cerebral palsy

Children are still admitted to hospital, especially lon stay hospitals, because of primary tuberculosis This i occasionally necessary for social reasons, but there is n special treatment which is given in hospital for thes children which cannot be given at home

One feels that fewer children should be admitted t hospitals for infectious diseases Except when there ar difficult social circumstances, the great majority of case of uncomplicated measles and scarlet fever should b nursed at home If there are other children in the hous they will have been exposed to the infection before th infected child was sent to hospital, so isolation wi achieve little Furthermore, it is irrational to sen children with scarlet fever to an infectious-disease spital while other children with streptococcal tonsillitis e nursed perfectly well at home

More effective use of the public-health services, in- uding especially health visitors and home helps, can do uch to prevent unnecessary admission to hospital—at ormous saving of expenditure, apart from the advantage the child Immunisation against infectious diseases, ich as whooping-cough and poliomyelitis, can be xpected to do much to reduce hospital admission They ay also be reduced by home-care schemes, such as that stablished many years ago by the Leeds Public Dispensary nd Hospital, and the one developed later by St. Mary's Iospital, London

PREPARATION FOR ADMISSION

If a child is old enough to understand, he should be old a little of what he will see in hospital—about caps nd gowns, nurses and doctors, and so on He should be varned that he may be put into a cot, even though he has ong since graduated to a bed, for otherwise he may be adly offended It would often be of value to allow the hild to see the ward and meet the ward sister before his dmission Various hospitals have prepared pleasant ooklets which can be shown to the child, and some of hem are suitable for crayoning They include the Hospital of the South Bay, California, the Health Centre, Vancouver, the County Hospital, Lincoln, and the Whittington Hospital The Central Council for Health Education publishes a leaflet for the purpose There is good scope for more really pleasant booklets on the subject

Preparation of the child must not be prolonged or excessive, neither must it be neglected The difficulty is in striking the happy mean, and it is very much a matter of opinion In general, I feel, two or three days' preparation should be adequate Too long or excessive conversation about the hospital is apt to cause anxiety in the child It is quite wrong to go into *details* of operations, such as tonsillectomy, which are quite beyond the child's comprehension and can only lead to unpleasant fantasies and fears in an imaginative child The emphasis should be on the pleasant side of hospital life rather than the unpleasant experiences which the child may face

In some research projects (e g, Albany) a social worker has visited the home on several occasions to prepare the child This would hardly be practicable in ordinary hospital practice

A leaflet for the parents can be of some value It should describe visiting-times, the purposes of the visit, the importance of not making promises (about the child's return home) which will not be fulfilled, the provision of suitable toys, and the sending of letters by parents and friends

ADMISSION PROCEDURE

It should never be necessary to drag a screaming child away from his mother in the casualty or outpatient department The mother should go up to the ward with her child and see him into bed, if possible staying a short time with him until he has had a chance to see his new surroundings Ideally a child who is well enough should be admitted not to the ward but to the ward playroom The traditional bath on admission can sometimes be avoided The child should take with him his favourite teddy, bit of rag, or toy The immediate [illegible] his clothes may cause anxiety

THE TYPE OF HOSPITAL

Whenever possible, a child should be admitted to a children's hospital rather than to a general hospital This is obviously impossible if the town is not large enough to justify a separate children's hospital The advantages of a children's hospital compared with a children's ward in a general hospital are numerous there are fewer changes of nurses, the nurses are trained in children's work, including the psychological aspects of children's nursing, there will probably be better toys and play equipment, occupational therapists and members of all the ancillary services, such as physiotherapy and speech therapy, are more accustomed to work with children, and the laboratories are likely to use micromethods instead of those requiring more venepunctures

For these and many other reasons there is everything to be said for a separate children's hospital—preferably very near an adult hospital, so that there is constant contact between the two hospitals I agree entirely with the report of the Royal College of Physicians (1957) which said "There is no doubt that special children's hospitals offer the best service for children, because the staff, at all levels, and in all departments, is attuned to the special needs of the sick child"

Except where it is really necessary, children should not be admitted to infectious-diseases hospitals Each [illegible] hospital and each children's hospital should have its own isolation unit, where cases of infectious disease [illegible] and where children requiring specialised [illegible] those with gastroenteritis) can be treated [illegible] with experience of these problems The [illegible] Physicians report stated that "in every [illegible] isolation accommodation is essential, [illegible] developed a block should be included [illegible] We all know, furthermore, that a [illegible] children admitted to infectious [illegible] suffering from infectious disease [illegible] understand why so many cases [illegible] meningitis are sent to them.

Children should certainly [illegible] wards This is particularly [illegible] Physicians report. [illegible] things which they should [illegible] logical trauma, the [illegible] adult patients and [illegible] have an adequate [illegible] tional therapy and [illegible] a children's [illegible] other children

If there [illegible] should be a [illegible] is no [illegible] is [illegible] of [illegible]

In general, children should not be admitted to single cubicles, except where there is a special reason for it—e g, infectious disease—and even then there may be several children with the same infection who can be together in a small ward Cubicles are desirable for babies but undesirable for older children unless the circumstances are exceptional Children are far happier in a ward with other children than in a room of their own in a private block or in a nursing-home (On seeing a depressed-looking boy in a single room in a private block, a consultant remarked to his resident "Poor little rich boy,") The aim of cubicles is the prevention of cross-infection We all know how regrettably they fail to achieve this Apart from this, one has to balance the risk of cross-infection against the psychological trauma of solitary confinement If a cubicle has to be used, the glass should reach down to the child's eye level, so that he can see others from where he lies in bed

If a child has to be admitted to a hospital a second time, he should be admitted to the same hospital and to the same ward as before A combined medical and surgical ward helps to make this possible It helps the child, because he knows the sister in charge

Transfers of children to other hospitals for specialised treatment are difficult to avoid but should be kept to a *minimum The difficulty lies in the expense of providing* specialised equipment in more than one hospital in a group In a city, however, much can be done by concentrating children in one children's hospital, rather than in several scattered units none of which are large enough to justify the provision of equipment and personnel for the various subspecialties

Each children's unit should have accommodation for mothers, as advocated by the late Sir James Spence, so that a mother can be admitted with her child if she is particularly disturbed about being separated from him, or if he is likely to find the separation difficult, or if a child who has been admitted is not settling down satisfactorily This arrangement presents great psychological advantages to mother and child The mother nurses her own child under supervision and is helped by the confidence so acquired The arrangement is especially useful in the care of difficult feeding problems, in which a mother has lost confidence in her ability to feed her baby

When I told a mother that I wanted to admit her 3-year-old child, she said that she would give anything and do anything, such as scrubbing the ward floor, to be allowed to come in with her child I told her that she could have a room with her child without having to scrub the floor, but that she would help to nurse the girl Her gratitude was immense

Unfortunately, because of domestic difficulties, relatively few mothers can come into hospital with their child Moreover, when pressing them to come, one must remember the possible psychological trauma and jealousy in the children left behind, and balance it against the psychological trauma in the sick child if the mother does not come in with him Those left behind must not be forgotten

If a mother cannot stay the night, she can often come in for the whole day to look after and be with her child The provision of home helps should make this more easy

DAILY VISITING

All children's units should allow daily visiting There are still hospitals, particularly long-stay ones, which oppose it, mostly on the grounds that separation from the parents does no harm, and that children settle down better if not visited Their attitude arises largely failure to understand the psychological reactions children I have seen severe psychological problem lasting for years in children who have been in such long-stay hospital where visiting was not allowed each case the children, who were inpatients at the age 3 to 4, bore considerable *resentment against their parent* reminding them for several years that they "deserted" them when they were ill I heard of a 4-year-old chil who was an inpatient for ten *months in an infectiou* diseases hospital without being allowed to see his parent By the time he did see them he must have complete forgotten them

Some infectious-diseases hospitals have rigid rule about visiting Parents may be allowed to look at a chil through a glass partition This must be very tantalisin for a small child, who cannot understand why the parent do not enter the room I can see no reason why parent should not be allowed into the room of a child wit measles, and the same applies to most of the othe common infectious diseases

The arguments usually raised against daily visiting an the risk of cross-infection, the difficulty of one child no having a visitor when others do, and the idea that th child is upset by visits and is better without them A *for the first, several studies have shown that daily visitin* does not increase cross-infection The difficulty of one child not having a visitor when others do is a real one and difficult to answer, *but I do not agree* with the ide that there should be equal misery for all Tactfu handling by the nurses, with the traditional kindness o other visitors who see a child looking lonely, will hel such children As for the third objection, it is true tha most young children cry when their parents depart, bu this lasts only a short time, and it is far better tha children should be disturbed for a few minutes on th departure of their parents, with the certain knowledge (which they very soon acquire, even when very young that the parents will come every day, than that they should become more and more convinced that they have been deserted, or are being punished

In leaflets or booklets given to them by the hospital, parents may be told so much about the importance of daily visiting that they feel guilty when they cannot visit every day *In a previous paper* (Illingworth and Hol 1955) we pointed out that visits are often costly and take much time, and this must apply more in long-stay hospitals Parents can be helped to pay their fares by the almoner's department, but there is the real problem of the children at home Home helps, supplied by the health authority, may be part of the solution Once more one has to strike a balance between the psychological trauma and jealousy in the normal siblings at home and the needs of the sick child in hospital

The visits should preferably be in the evening, nea the child's bedtime, and should not be too short, but there should be considerable latitude for the sake of those *whose* work or domestic situation makes this difficult

For children spending a very long time in hospital occasional weekends at home are of considerable value

HOSPITAL DESIGN

We have much to learn from other countries—in particular, I would say, from Finland—about the design of children's hospitals The provision of a veranda for each bed, as at The Hospital for Sick Children, Great

Ormond Street, London, is desirable Ideally, each ward would have a playroom, or a combined eating-room and playroom It is necessary to give thought to making the outpatient, casualty, and X-ray departments attractive and colourful The latter department may be frightening for a child something can be done by pictures and toys to make it more attractive Large waiting-halls should be a thing of the past A small attractively equipped and decorated waiting-room in between each two consulting-rooms is much better Pleasant canteen facilities should be provided When parents who have attended a morning outpatient clinic with a child are asked to stay for another clinic in the afternoon, meals should be provided

INSTRUCTION OF NURSES AND STUDENTS

On the psychological aspects of child care nurses should get instruction from the pædiatrician and not from a sister-tutor who is divorced from practical ward work They should learn about the psychological development and management of normal children and the psychological needs of the sick child

Nurses should be told about their role as temporary mother-substitutes and be encouraged to pick children up, instead of turning a deaf ear to their crying They must be told that the small child who stands at the end of his bed with his nappie half-down his legs and with a running nose, screaming all day long, is not a naughty spoilt child but a normal one, and that the quiet subdued 2-year-old who lies in bed all day without a murmur is not being "good" (when he is normally a boisterous, noisy, happy child) but is showing an abnormal and undesirable reaction as a result of emotional deprivation They must be told to avoid such errors as forcing food, taking the temperature by the rectal route, giving an enema before an operation, making a fuss about an "accident", or giving children unsuitable clothes, such as a girl's nightie for a 10-year-old boy, or a pyjama jacket without pyjama trousers They must be told about the importance of attending to children's toilet needs (just as one would at home), of keeping them occupied, of arranging them in suitable age-groups (particularly the older children), and of seeing that when they have to be readmitted they come back to the same ward as before They must be told about the importance of never lying to a child (especially in saying that a painful procedure, such as an injection, will not hurt), and of telling him what is going to happen—not long before, but just before it is done In fact, nurses have to be instructed in all the points mentioned in this paper

KEEPING CHILDREN OCCUPIED

Nurses should be instructed in the selection of toys and books for different age-groups At the Children's Hospital, Sheffield, they all receive a lecture and practical demonstration on the subject They should be told about the importance of seeing that the children have plenty to do They should be brought to realise that a well-managed children's ward should be thoroughly untidy

I have been impressed in travels abroad by the lack of provision of toys for children in hospitals In this country the provision of toys for the younger children is apt to receive insufficient attention

Every children's ward has its 240-piece jigsaws and books about naughty girls at school who turned out well, but one rarely sees wards equipped with 10-piece or 20-piece jigsaws, with dolly-dressing equipment, or with books suitable for the child aged 5 to 6 who has lately learnt to read. Furthermore, a nurse who has been properly instructed should be able to advise parents about toys and books suitable for children Parents are apt to bring mechanised toys, often quite expensive, which are of little value to a child, because they give no scope to his imagination I have dealt with the question of toys for different age-groups elsewhere (Illingworth 1957)

It would be a good thing to have one person, perhaps someone in the department of occupational therapy, who would go round every ward every day with a trolley-load of toys She would take responsibility for them and try to reduce the prevalent high loss-rate Another, perhaps a nursery-school teacher, might be responsible for the children's books, advising on their purchase and taking them round to the wards Voluntary workers could well take up this pleasant occupation

For children who are sufficiently well, out-of-doors equipment—e.g, sandpit, climbing-frame, and wheeled vehicles—could be provided A roof garden might be used for the purpose

A department of occupational therapy, in which nurses receive instruction as part of their training, is an essential part of a children's hospital The occupational therapist must avoid the temptation of concentrating on the older children, who are better able to look after themselves than are the younger ones The occupational therapist should be on call for any newly admitted child or any child who is unhappy New admissions should be seen by the occupational therapist as soon as possible after coming to the ward—not next day

Teachers are now provided by the education authority in most children's units in this country These teachers greatly help children in hospital by keeping them occupied and preventing psychological trauma as a result of backwardness on return to school They teach short-stay children as well as long-stay ones

I feel that a doctor should be responsible for supervising the arrangements and the supply of suitable and adequate toys for the children The matter is of considerable psychological importance, and, if he does not take an interest in the matter, it may well be that no one else does

A television set in each ward is appreciated

PROVISION OF SUITABLE FOOD

A resident doctor should be expected to keep an eye on the food supplied to children Imagination is required to make food attractive in appearance and palatable for children Too often the child is expected to enjoy a nondescript mush, or a daily diet of minced meat and mashed potatoes, followed by milk pudding Among other items a liberal supply of fresh fruit and ice-cream is likely to be welcomed, and chips are usually popular

UNPLEASANT PROCEDURES

By a little thought much can be done to minimise unpleasant procedures For instance, when one is about to give an injection or to take blood for a laboratory investigation, the preparations for the prick should be concealed from the child One sees a child wincing at the sight of the needle and syringe being made ready By judiciously standing with one's back to the child and between the child and the syringe, he can be prevented from seeing the preparations Much can be done by getting the equipment ready in another room before approaching him

There is a tendency to carry out many investigations one after the other, all requiring pricks, instead of doing a batch at one time from one specimen A little forethought will prevent such a succession of investigations and avoid those which will throw no light on the problem

In the same way a succession of anæsthetics can often be avoided Venepunctures for laboratory investigations may be done when the child is under an anæsthetic for another purpose

The era of painful daily dressings has now largely gone, and wounds are given a chance to heal without being damaged by daily interference Few unpleasant experiences in hospital can have caused so much psychological trauma as they did There is still room for thought, however, about the avoidance of such painful procedures, or about the use of a tranquillising drug when a painful procedure is necessary in an anxious child

Now that depot penicillins and more satisfactory oral preparations are available, repeated injections of aqueous penicillin should be a thing of the past, except in certain rare special circumstances The increasing use of micromethods is reducing the number of venepunctures in children's hospitals, but some hospitals have a long way to go in their use

The use of premedication before anæsthesia is a matter for further investigation

There are advantages and disadvantages which cannot be discussed here There is much truth in the comment by Jackson et al (1952) that "our experience has shown that the child best able to meet the hospital-anæsthesia-surgery situation is the child who is able to trust the physician and nurses to treat him fairly", and "the child who is anxious and suspicious is the child who will cry and resist the most" Nevertheless, one has to try to reduce psychological trauma in children who are insecure as a result of unsatisfactory home relationships or who are of a nervous type, and for them premedication may be advisable It may help to allow a child to take his favourite toy to the anæsthetic room There is a great need for careful experiments of the "blind" variety to determine the best method of preparing children for anæsthesia

Trauma from mechanical procedures can be reduced by the appointment of doctors for resident appointments who have had previous appointments in adult wards

SIGHTS AND SOUNDS

Children in a ward should not be allowed to see another child suffering, to see death, to see unpleasant procedures being applied to another child, or to see a child bringing up blood after a tonsil operation The proper use of a treatment room, and the use of a cubicle for a dangerously ill child, will prevent much of this

Great care should be taken to avoid talking in front of children about their ailments It is very easy to err in this direction during a ward round It is a mistake to think that the use of long words provides safety in this direction Children hear and misinterpret what they hear I saw a boy who had been seriously disturbed because he had been told (in an adult ward) that the patient in the next bed to his was not going to get better An inexperienced nurse could easily say this without thought

One must remember the foolish conversation in a ward between one child and another Hence all the children should be prevented from seeing and hearing things which they should not hear, because otherwise details of unpleasant happenings or sayings will soon be embroidered and exaggerated, and so lead to anxiety

CONFINEMENT TO BED

It is difficult to determine why children are kept in bed so long in many illnesses The most likely explanation in many cases lies in the fact that no-one has thought of getting them up The number of medical conditions demanding strict confinement to bed is very small indeed

A high proportion of children in the medical wards have been admitted because of respiratory infections There is no justification for keeping them in bed after their temperature has become normal or nearly so Gibson (1956) conducted an interesting study of the effect of rest in bed on children with these infections at home Those who were up and about their room, in spite of slight pyrexia, fared quite as well as those who stayed in bed A child who is feeling poorly because of an infection wants to be in bed and should stay there, whereas a child who is anxious to get up should usually be allowed to do so A child is far happier if allowed to sit in a chair near a fire, playing games with other children, and having his meals out of bed, than if he is confined to bed all day In any case an active child who is feeling well is likely to exert himself much less if allowed to sit at a table in the ward than if he is restlessly jumping about in the bed Children, like adults, much prefer to go to a lavatory than to be compelled to use a bedpan, and few medical conditions necessitate the deprivation of the right to go to the lavatory The children's doctor should pay special attention to the question of stay in bed

ROLE OF THE FAMILY DOCTOR

In many practices family doctors visit their patients in hospital Children who know the doctor are helped in this way The doctor, furthermore, helps the parents by reporting progress and confirming what they have been told themselves

THE ROLE OF THE PADRE

The hospital padre can help to reduce psychological trauma in children by talking to them and by holding ward services There should be contact between the padre and the parents of the children

EARLY DISCHARGE

With care and thought the duration of stay in hospital can be greatly reduced below its present figures, particularly if proper use is made of the public-health services, including the health visitor and the district nurse In my opinion a constant conscious effort should be made to reduce hospital stay At the Children's Hospital, Sheffield, when a child is admitted for operation on an inguinal hernia, he is admitted in the morning, operated on in the afternoon, and discharged home next day

The problem of carriers of pathogenic intestinal organisms, such as those of Sonne dysentery and the salmonella group, should be considered by the public-health authorities The problem involves the long stay in hospital of otherwise perfectly well children

DISCUSSION WITH THE PARENTS ON DISCHARGE OF THE CHILD

All parents should be seen by the doctor during the child's stay in hospital and on his discharge Not only must they be told about his illness but also they need to be advised about possible difficulties in behaviour They must be warned not to spoil him because he has recovered from an illness, he must be treated as a normal child and subjected to the same discipline as anyone else Anxiety must not be shown if he wets his bed They must be told that, if any regression symptoms or symptoms of insecurity appear—clinging, temper tantrums, fears or sleep disturbances—they should be tackled by treating the basic cause, the feeling of insecurity Every effort should be made to give the child a feeling of importance and of being wanted and loved, reprimands being absolutely avoided if possible

The doctor should always make sure that the parents have had a full opportunity to ask any questions they wish

AVOIDANCE OF PARENTAL TRAUMA

This indirectly benefits the child The role of accommodation for the mother in a room with her child, arrangements for the mother to stay during the day, and of daily visiting have already been mentioned The admission procedure is also important the avoidance of trauma to child and mother by separating a crying child from his mother in the outpatient department has been emphasised

Mothers should not be expected to witness unpleasant procedures I heard of a mother being asked to hold her child down while painful daily dressings were made It is doubtful whether a mother should see her child coming out of an anæsthetic, particularly after tonsillectomy, though it has psychological advantages to the child

Good liaison between parents, nurses, and doctors achieves a great deal in the reduction of trauma Parents should always feel that they can obtain all the information they want, and that they know what is being done and going to be done Above all things, nurses and students must be taught never to tell a mother that she is being "fussy" or "overanxious" A good mother *is* anxious about her child

GOITRE AND ARTERIOSCLEROSIS

Unto Uotila
M D
PROFESSOR OF FORENSIC MEDICINE

Jyrki Raekallio M D
Wilhelm Ehrnrooth M D
ASSISTANT PHYSICIANS, INSTITUTE OF FORENSIC MEDICINE
UNIVERSITY OF HELSINKI, FINLAND

Our interest in the ætiology and pathogenesis of arteriosclerosis and atherosclerosis was aroused by our observation at forensic necropsies that persons who had died from coronary sclerosis often had a goitre We have had the principal organs weighed over a period of several years and have been able to demonstrate that goitre is in fact significantly commoner in people who have died of coronary sclerosis than in those who have died from other causes

Much has been published on the connection between the thyroid gland (especially in hypothyroidism) and experimental atherosclerosis (Andrews 1953, Katz and Stamler 1953) It shows that in hypothyroidism there is not only hypercholesterolæmia but also a tendency to arteriosclerosis, and that thyroid hormone can decrease both exogenic alimentary cholesterolæmia and atherosclerosis There is also some clinical and postmortem evidence of a tendency to atherosclerosis in *myxœdema* (Fishberg 1924, Rosenthal 1934, Bruger and Rosenkrantz 1942, Means 1948, Kountz 1950), though some workers, such as Andrews (1953), have thought this inconclusive

The relationship of goitre and coronary sclerosis has been discussed in listing the indications for goitre resection in the presence of coronary-artery disease But we have found no reference in the literature to the possible ætiological relationship of the two conditions

Material and Methods

250 deaths from coronary sclerosis and its consequences were selected from the material of the Institute of Forensic Medicine at Helsinki, 200 of them in men and 50 in women In another 200 men and 50 women selected as controls the causes of death were either natural or violent —the only principle observed in the selection being to obtain a case as free as possible from coronary sclerosis This involved the examination of thousands of cases Each age-group of 5–10 years included equal numbers of coronary-sclerosis deaths and controls

In each case all the principal organs were weighed after careful preparation A thyroid gland weighing more than 40 g was regarded as a goitre because this seems to be the natural limit in Finland where goitre is of medium endemicity (Wahlberg 1938, Uotila 1942)

Results

The height of the patients in the coronary-sclerosis group did not differ statistically from that of the controls, but on the average they were somewhat shorter (table I) The coronary-sclerosis males tended to be heavier than their controls, but no significant difference was found in body-weight in the women The weight of the men with coronary sclerosis and goitre, however, was significantly heavier than the men with coronary sclerosis but no goitre (P=0 002)

TABLE II—FREQUENCIES OF SOME CHANGES

—	Coronary-sclerosis group (%)	Controls (%)	P	
Goitre (thyroid more than 40 g)				
Males	58	28	0 0005	0 0005

Males	7	4	>0 5	0 4
Females	26	20	>0 4	

The weights of the pituitary gland, the adrenal glands, the gonads, the pancreas, and the spleen of the coronary-sclerosis group did not differ significantly from those of the controls (table I) The thyroid gland, on the other hand, weighed more in the coronary-sclerosis group The incidence of goitre (i e , thyroid gland weighing more than 40 g) was 58% for coronary-sclerosis males against 28% for male controls, and 50% for coronary-sclerosis females against 22% for female controls The difference was statistically very highly significant (table II)

As the coronary-sclerosis group and the controls were matched for age, there was no difference in their average ages The average age both of the coronary-sclerosis males with goitre and of the coronary-sclerosis males without goitre was 55 The χ^2 test of the cumulative percentage age-distribution showed a difference for the men in the over-65 group (P=0 02) In the women, the average age of the goitrous coronary-sclerosis case was 65 and of the non-goitrous coronary-sclerosis case 68, the difference of age-distribution in the χ^2 test being statistically significant (P=0 001)

That the heart weighed more in the coronary-sclerosis group than in the controls was to be expected, but it is significant that it weighed more in the goitrous coronary-sclerosis cases than in the non-goitrous (P=0 002)

The liver and the kidneys of the coronary-sclerosis group were heavier than those of the controls, but there was no correlation between their weight and the presence or absence of goitre Finally, mention must be made of the higher incidence of general arteriosclerosis in the coronary-sclerosis group compared with the controls (table II)

Discussion

It is easy to understand that coronary sclerotics are somewhat shorter and heavier than other people, because most patients with coronary sclerosis belong to Kretschmer's pyknic type The fact that coronary sclerotics with goitre weigh more than those without goitre suggests that the thyroid gland may be responsible The finding that in coronary sclerotics the heart is bigger in those with goitre than in those without goitre points in the same direction If the thyroid is involved in the ætiology of coronary sclerosis, is this through toxicity of the thyroid secretion or hypofunction of the gland, or some factor not yet known ?

The heavier liver and kidneys of coronary sclerotics are usually explained by stasis due to heart-failure, but this explanation seems somewhat lame when one finds no corresponding increase in the weight of the pancreas and the spleen

As coronary sclerosis and arteriosclerosis are largely concomitant, it is justifiable to identify them to some extent

We considered the possibility that the high incidence of an abnormally large thyroid gland (i e , goitre) could result from stasis, but we concluded that this is extremely unlikely, since the weight and incidence figures of goitre and coronary sclerosis bear too significant an interrelationship The age-distribution of goitrous and of non-goitrous cases of coronary sclerosis supports this conclusion A more specific relationship is also indicated by the influence of goitre on the weights of the body and of the heart in cases of coronary sclerosis Finally, our view is supported by the fact that the iodine content of food is smaller (Vilkki 1956, Roine et al 1958) but coronary sclerosis more common (Keys et al 1958) in eastern Finland, where endemic goitre is more prevalent (Wahlberg 1938) than in western Finland

The close association between goitre and arterio-sclerosis suggests a causal relationship It might be thought that coronary sclerosis, through the stress it originates, causes involution of the thyroid gland and produces colloid goitre (Selye 1950, Isotalo), but this explanation seems rather far-fetched, especially in the light of the facts about goitre in Finland which we have just mentioned

The association between coronary sclerosis and goitre can, we think, be explained differently The Finnish *endemic goitre is hypoepithelial—i e , in 60%* of cases its *content of epithelium is less than 25%, owing to abundant* colloid and fibrosis (Saarenmaa 1956) Furthermore, it is usually nodular In the Joensuu district in eastern Finland the level of protein-bound iodine in the serum was 2–3 μg per 100 ml in 6 1% of those with goitre and 2–4 μg in 21 3% (Jussila) The corresponding figures for Helsinki are 5 3 and 18 1% respectively (Lamberg et al 1956) Also in view of the fact that goitre (i e , thyroid gland weighing more than 40 g) occurs in 45% of all the necropsy material of the Institute of Forensic Medicine, *Helsinki, it is probable that endemic goitre in Finland has some hypothyroid features*

In hypothyroidism an excessive amount of thyrotrophic *hormone is secreted In addition* to its stimulating effect *on the thyroid gland, thyrotrophin affects* connective tissue directly by increasing its mucopolysaccharide content (Asboe-Hansen and Iversen 1951) It also prevents the maturation of granulation tissue whereas growth hormone promotes it (Saikku 1956) We think it likely that the acknowledged tendency of hypothyroid patients to arteriosclerosis is attributable not only to raised serum-cholesterol level but also to the overproduction of thyrotrophin

It is generally believed that endemic goitre is caused by hypertrophy and involution, this means, at some stage or other, overproduction of thyrotrophin According to Lamberg et al *persons with goitre in the* Aaland Islands have a greater amount of pretibial acid mucopolysaccharides than do healthy persons, and this might be attributable to overproduction of thyrotrophin

Summary

Postmortem findings in *250 persons who died* of coronary sclerosis are *compared with the findings* in 250 persons *who died from other* causes

Goitre was commoner, and the average weight of the thyroid was higher, in those with coronary sclerosis *Among the coronary-sclerosis* cases, those with goitre had a tendency to lower average age at death and a higher average heart-weight

Comparison of body-build showed that the 250 persons with coronary sclerosis were slightly shorter and heavier than the controls Among those with coronary sclerosis those with goitre were heavier than those without goitre These findings are correlated with observations made in Finland on the nature and distribution of endemic goitre, the iodine content of the food, and the distribution of coronary sclerosis

It is concluded that goitre and arteriosclerosis may have a pathogenetic relationship, possibly through hypothyroidism and the overproduction of thyroid-stimulating hormone by the pituitary gland

This work was aided by an institutional grant from the Damon Runyon Memorial Fund for Cancer Research, New York (DRG 290 A/T), from the Sigrid Juselius Foundation, Helsinki, and from the Natural Science Research Council, Helsinki, to the Institute of Forensic Medicine, University of Helsinki

In the epidemiology of cardiovascular disease Finland is of special interest (Keys et al 1958) because the mortality of men from coronary disease is higher there than in any other European country, and mortality and disability statistics suggest that cardiovascular disease is more prevalent in the eastern than in the western part of Finland Keys et al (1958) have also shown that serum-cholesterol levels in Finland are unusually high, particularly in the eastern part Since there is much evidence that diet plays a part in the ætiology of coronary disease, it is important to get reliable information about the diets in these areas and, in particular, to know if dietary differences can be related to different incidences of coronary disease Dietary surveys were therefore made in selected areas of West and East Finland in connection with the medical studies of Keys et al (1958)

TABLE I—ANALYSIS OF FAMILIES INCLUDED IN FINNISH DIETARY SURVEY

—	1956		1957	
	East	West	East	West
Number of families	42	42	20	20
Mean number of persons in each family	4 3	4 4	3 9	4 1
Mean age of adult men (yr)	40 4	39 7	45 3	38 9
Mean age of adult women (yr)	41 0	38 8	43 0	40 8
Mean age of those younger than 20 (yr)	8 1	8 0	9 7	8 1

The greater part of the dietary survey was made in June, 1956, but to get some idea of the seasonal variations half the families were studied again in January, 1957 Forty-two families from the West and the East, mainly of farmers of fair financial standing, were included in the study Almost all the men in the families did heavy physical work (grades 3 and 4) The number of people in the families was 358 (0 7–0 8% of the population of the communities)

TABLE II—SERUM-CHOLESTEROL LEVELS (MEAN ± STANDARD ERROR) OF MEN IN DIETARY SURVEY COMPARED WITH THOSE IN ENTIRE MATERIAL (KEYS ET AL 1958)
(All samples were taken in September, 1957)

Group	Age (yr)			
	20–29	30–39	40–49	50–59
East				
Men in dietary survey	226±23 9 *(4)*	252±16 7 *(12)*	247±16 3 *(13)*	250±21 2 *(11)*
Men in work grades 3 and 4	215±6·9 *(40)*	263±8 0 *(57)*	251±5 9 *(57)*	252±7 6 *(31)*
West				
Men in dietary survey	220±24 3 *(4)*	222±11 2 *(17)*	248±14 8 *(13)*	279±19 3 *(7)*
Men in work grades 3 and 4	204±7 1 *(50)*	223±5 2 *(52)*	239±7 4 *(48)*	248±7 5 *(39)*

Numerals in parentheses denote number of persons

The groups of families in each area were matched as closely as possible A comparison of the groups is presented in table I

An attempt was also made to select the families in the dietary survey to represent the same populations as in the serum-cholesterol study (Keys et al 1958) The extent to which this was achieved may be judged with the aid of the serum-cholesterol levels, a comparison of the men in the dietary survey with those in the larger group is

TABLE III—AMOUNTS OF MAJOR FOODSTUFFS CONSUMED IN WEST AND EAST FINLAND
(g per caput per diem)

TABLE IV—AMOUNTS OF PROTEINS, FATS, CARBOHYDRATES, AND CALORIES IN DIETS OF WEST AND EAST FINLAND
(Per caput per diem)

—	Summer 1956			Winter 1957		
	West	East	P	West	East	P
Proteins (g)	78 6	86 9	0 05	79 1	82 9	>0 25
Fats (g)	99 3	102 7	>0 25	98 9	105 0	>0 25
Carbohydrates (g)	357	348	>0 25	346	376	>0 25
Total energy (kcal)	2598	2636	>0 25	2549	2732	0 25
Energy from proteins (%)	12 1	13 2		12 4	12 1	
Energy from fats (%)	34 4	35 0		34 9	34 6	
Energy from carbohydrates (%)	53 5	51 8		52 7	53 3	

presented in table II, which shows that the serum-cholesterol levels of the men in the dietary survey do not differ significantly from those of the men in the larger groups

The distribution of food items within each family was not studied The men's share of the food consumed was naturally more than the average for each member of the family, and there may have been some selection of food items within each family Nevertheless the qualitative character of the diet of a family probably is a satisfactory indicator of the diet of the men

The food consumption was determined by weighing—i e, special investigators weighed during seven days all the items used in the preparation of foods, during meals, and between meals, as well as refuse and table waste

TABLE V—LIPIDS IN DIETS OF WEST AND EAST FINLAND
(Per caput per diem)

—	Summer 1956			Winter 1957		
	West	East	P	West	East	P
Animal fats (g)	83 3	91 2	0 1	81 5	90 5	0 25
Vegetable fats (g)	16 0	11 5	0 001	17 4	14 5	0 25
Fatty acids (g)						
Saturated	53 0	56 5	0 25	52 3	56 5	>0 25
Mono-enes	33 6	33 9	>0 25	33 7	35 5	>0 25
Linoleic	6 7	6 3	0 25	6 8	6 8	
Other poly-enes	1 2	0 9	>0 25	1 3	1 2	>0 25
Cholesterol (mg)	402	375	>0 25	383	363	>0 25

Accurate information about the foods actually consumed was thus obtained

The figures of food consumption, which give an idea of the Finnish dietary in general, are shown in table III A comparison of the figures for the West and those for the East shows, among other things, a higher consumption of bread, milk, butter, and fish in the East, and of vegetables, margarine, and eggs in the West

The calorie values of the diets, as well as the amounts of protein, fat, carbohydrate, calcium, iron, vitamin A, aneurine, riboflavine, nicotinamide, and ascorbic acid, were calculated according to Finnish food consumption tables (Turpeinen and Roine 1952) For iodine recent analytical values of foodstuffs in West and East Finland were available (Vilkki 1956) In the calculation of fatty acids of butter fat Finnish values of Peltola (1944) were used Fatty-acid figures for most typical margarines used in the country were obtained from analyses kindly mad by the Research Division of the Miami Valley laboratorie of the Procter and Gamble Company in U S A Othe nutrients were calculated according to estimates fixe after an extensive survey of the literature

Table IV shows that the amounts of proteins are usuall large, and there seems to be a significant differenc between West and East in the summer survey Th energy values are in all cases very much alike A high percentage of energy, about 35%, is derived from fats,

TABLE VI—AMOUNTS OF SOME AMINOACIDS, VITAMINS, AND MINERALS IN DIETS OF WEST AND EAST FINLAND
(Per caput per diem)

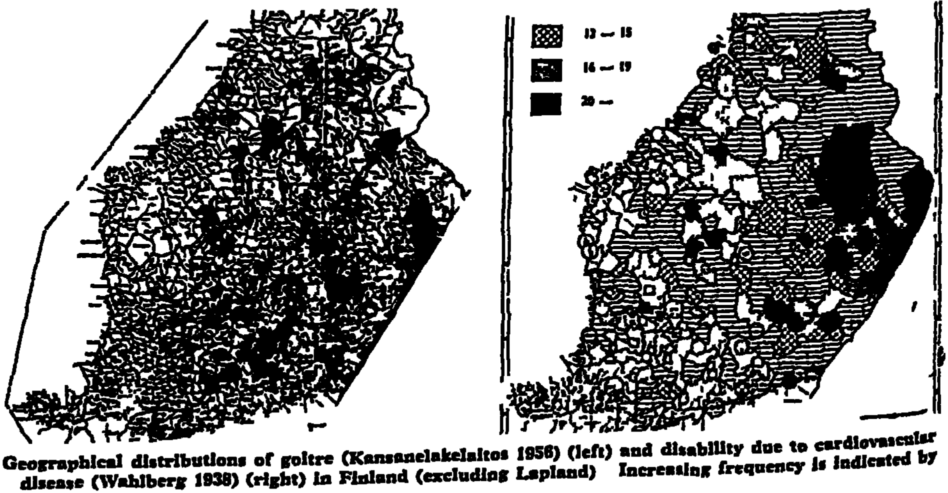
—	Summer 1956			Winter 1957		
	West	East	P	West	East	P
Cystine (g)	0 84	0 88	>0 25	0 83	0 88	>0·25
Methionine (g)	*1 66*	*1 71*	*>0 25*	*1 69*	*1 69*	
Vitamin A (I U)	2840	2780	>0 25	3270	2820	0·1
Vitamin E (mg)	9 90	9 21	0 1	11 10	9 73	0·05
Thiamine (mg)	*1 51*	*1 53*	*>0 25*	*1 57*	*1 69*	>0·25
Riboflavine (mg)	2 33	2 74	0 01	2 26	2 48	0·25
Nicotinamide (mg)	12 1	11 5	>0 25	12 8	13 6	>0 25
Pyridoxine (mg)	2 89	3 08	0 25	2 79	3 04	>0 25
Pantothenic acid (mg)	6·41	6 50	>0 25	6 28	6 45	>0 25
Choline (mg)	695	645	0 1	734	668	*0 25*
Ascorbic acid (mg)	56	46	0 002	68	*54*	*0 05*
Calcium (mg)	*1199*	*1406*	*0 01*	*1204*	*1219*	*>0 25*
Iron (mg)	11 7	11 9	>0 25	12 4	12 5	>0 25
Iodine (µg)	71	55	0 001	62	51	0 02

but there are practically no differences between West and East in this respect and no seasonal differences either

Table V shows that more vegetable fats were consumed in the West than in the East, in summer the difference was highly significant Because the vegetable fat is mainly margarine, this difference has, however, very little effect on the fatty-acid values Saturated acids were consumed somewhat more in the East and linoleic acid and other poly-enes in the West, but differences are not significant A noteworthy fact is the large intake of saturated acids compared with the small intake of poly-enes, in the West this ratio is 6 6, in the East 7 5 The " cholesterogenic" formula (Keys et al 1957)

$$x = 2 \times g \text{ saturated fatty acids} - g \text{ poly-enes},$$

gives x=105 8 (1956) and 105 0 (1957) for the East, and x=98 1 (1956) and 96 5 (1957) for the West



Geographical distributions of goitre (Kansanelakelaitos 1956) (left) and disability due to cardiovascular disease (Wahlberg 1938) (right) in Finland (excluding Lapland) Increasing frequency is indicated by darker shade

Hence the dietary fat may be expected to raise the serum-cholesterol level higher in the East than in the West, which is in agreement with the actual observations (Keys et al 1958)

Figures for some aminoacids, vitamins, and minerals are given in table VI, which shows that there are no significant differences between West and East in the intakes of cystine and methionine or of most of the vitamins and minerals Ascorbic acid, however, was obtained in significantly greater amounts in the West—and vitamin E, at least in winter, too Riboflavine and calcium, on the other hand, were obtained in summer in greater amounts in the East

The iodine content of the diets deserves special attention All the iodine intakes are low, and there is a highly significant difference between West and East—findings which agree well with those of Virtanen and Virtanen (1940) and Vilkki (1956) Endemic goitre is common in Finland, particularly in the East At least a part of this goitre is of hypothyroid type (Uotila et al 1958) Since hypothyroidism raises the serum-cholesterol level, the low iodine content of the diet may contribute to the high serum-cholesterol values in Finland in general and in East Finland in particular The geographical distributions of goitre and of disability due to cardiovascular disease (see figure) show in Finland a striking parallelism The necropsy findings of Uotila et al (1958) also support the hypothesis that lack of iodine and resulting goitre are involved in atherogenesis in Finland

Summary

To find out if the higher incidence of cardiovascular disease in East compared with West Finland is due to dietary differences, dietary surveys were made in two selected areas of the country The food consumption during seven days of eighty-four families in summer and forty families in winter was determined by accurate weighing, and the daily calories and nutrient intakes per caput per diem were calculated

The average amount of fat consumed each day was 98 9 g–105 0 g per caput, being very similar in West and East and in summer and winter The mean percentage of energy derived from fats was within the limits of 34 4% and 35 0% The intake of saturated fatty acids was a little larger in the East, and that of linoleic acid and other poly-enes in the West, but these differences were not statistically significant In both cases the intake of saturated acids compared with that of poly-enes was rather large The ratio of saturated acids to poly-enes was higher in the East than in the West

Considerable differences were found in the amounts of iodine, ascorbic acid, and vitamin E, the intakes of which were significantly larger in the West The low iodine content of the diet, causing hypothyroidism and thus a rise in the serum-cholesterol level, might be partly responsible for the high serum-cholesterol levels and coronary mortality in Finland in general and in East Finland in particular

MORTALITY ascribed to cardiovascular, particularly to coronary, disease is higher in Finland than in other European countries (Kannisto 1951, World Health Organisation 1953) A very high incidence of coronary disease is shown by hospital admissions in Finland (Keys 1957) Arteriosclerotic heart-disease appears to be particularly common in East Finland, regional differences within Finland are indicated both by mortality-rates (Kannisto 1947) and by the statistics of the Finnish National Pension System on disability (Kansaneläkelaitos 1956) Fig 1 illustrates geographical differences within Finland in mortality ascribed to cardiovascular disease among men aged 30–59 Table I shows the morbidity-rates

The data on Finland, in which the population is predominantly engaged in agriculture and lumbering, are surprising in view of the widespread belief that coronary disease is relatively uncommon in physically active rural populations In Finland coronary disease is common among farmers and woodcutters Preliminary surveys in East Finland recently disclosed that myocardial infarction accounts for about 10% or more of male patients in the medical departments of hospitals caring for the rural population This finding and the morbidity-rates in table I stimulated a closer examination of the situation in rural East and West Finland with attention to the diet and the serum-cholesterol levels

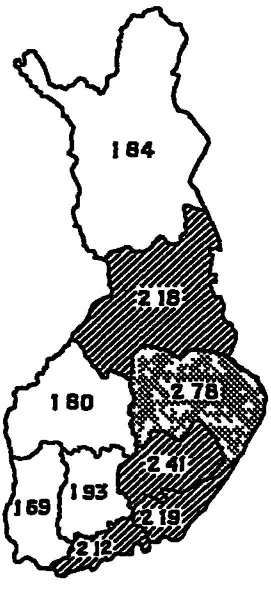

Fig 1—Mortality ascribed to arteriosclerotic heart-disease (International List, Sixth Revision, nos. 420–422) in Finland (V Kannisto, unpublished)

Investigation

In the autumn of 1956 a field study was made in West Finland and in Karelia, the areas where the records show the greatest differences in the incidence of coronary disease In addition, in Helsinki, the fire brigade and a group of "directors" (business and professional men)

---

* This study was supported by grants from the Science Board of the State of Finland, from the Sigrid Jusélius Stiftelse, from the Finnish Heart Association, from the National Dairy Council (Chicago), from the Winton Companies Fund (Minneapolis), and from the American Heart Association.

TABLE I—FINNISH PENSION SYSTEM 1955 MORBIDITY-RATES OF MALES, PER 1000 INSURED, ON ACCOUNT OF CORONARY DISEASE, HYPERTENSION, AND OTHER HEART-DISEASES (KANSANELÄKELAITOS 1956)

District	Coronary	Hypertension	Other heart-disease
Helsinki	1 88	0 79	1 58
Kuopio	4 63	1 90	4 46
Turku	1 60	0 68	1 59

The populations considered here relate to Kuopio (East), Turku (West), and Helsinki Pension System Districts

were studied Altogether 976 clinically healthy men were examined, 869 being aged 20–59

In the rural areas names were drawn from a list of men of the desired ages in or accessible to the various preselected communities where local headquarters could be established Substantially all the men who were requested to appear for examination did so The Helsinki groups were less representative of that area The fire brigade was a preselected group, but self-selection within the brigade was not involved in the examinations The "directors" responded to invitation, few so invited refused, but bias from self-selection is not excluded from this group

Dietary surveys, which are separately reported, were made in both rural areas in June, 1956, and January, 1957 (Roine et al 1958) The serum-cholesterol levels of the adult members (about 160) of the households involved were measured then in addition to the main survey, reported here, in the autumn of 1957 The Helsinki studies were made in October and November, 1957

The programme included medical history, physical examination, anthropometric measurement, a 12-lead electrocardiogram, serum-cholesterol estimation, and a questionnaire about smoking The blood-serum was analysed for total cholesterol and for cholesterol in the α and β lipoprotein fractions separated by paper electro-phoresis (Anderson and Keys 1956) In a large number of samples the cholesterol was estimated both locally in the fresh material and in duplicates, air-dried on filterpaper, and flown to Minneapolis to assure full comparability with cholesterol values from other populations studied at, or similarly controlled by, the Laboratory of Physiological Hygiene

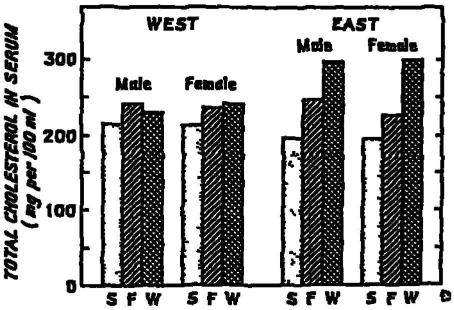

Fig 2—Seasonal variation in mean level of total cholesterol in serum of men and women in West and East Finland S, June, 1956; F, September, 1956, W, January, 1957

Results

Fig 2 shows the mean levels of total cholesterol in the serum of the persons of either sex in the dietary survey In the West the level rose significantly from June to September, but in the East this seasonal trend was larger and continued until January, when the average was about 100 mg per 100 ml higher than in June Accordingly, in comparing serum-cholesterol levels of populations, seasonal variations should be considered, at least in regions such as East Finland, where seasonal differences in climate and mode of life are extreme

The numbers of persons of given age, sex, and occupation are too small in the dietary survey to permit detailed analysis Table II summarises the serum-cholesterol levels of the 869 men studied in the autumn The rural men are classified according to level of occupational physical activity Grades 1 and 2 include sedentary and light work (clerks, teachers, car drivers, &c), and grades 3 and 4 cover hard to very hard physical work (farmers, blacksmiths, loggers, &c) On this scale the "directors" would be classed as grade 1 and the firemen as grade 2 or possibly between grades 2 and 3

The most obvious trend of the serum-cholesterol levels is that with age, the values for men in the twenties in all groups being lower than at older ages, the highest averages being in the forties in three groups, in the fifties in two groups, and in the thirties in the more active men in East Finland For the combined groups the mean serum cholesterol levels for successive decades of age are 212, 247, 257, and 258 mg per 100 ml This age trend is similar to that found elsewhere in populations characterised by relatively high serum-cholesterol levels (Keys et al 1950, Keys 1956)

TABLE II—MEAN TOTAL CHOLESTEROL (MG PER 100 ML) IN SERUM OF CLINICALLY HEALTHY MEN IN FINLAND CLASSIFIED BY DECADES OF AGE

Region and work grade	Age-group (yr)			
	20–29	30–39	40–49	50–59
East, grades 1 and 2	226±9 1 (28)	276±11 8 (24)	286±11 1 (24)	258±14 1 (14)
„ „ 3 and 4	215±6 9 (40)	263±8 0 (57)	251±5 9 (57)	252±7 6 (31)

Important regional differences were found At all ages and work grades the averages were higher for East (Karelia) than for West Finland, and these differences were particularly notable at ages over 30

These regional differences might be due to heredity or to environmental factors An attempt was made to elucidate the relative influence of these two factors by grouping the Helsinki subjects according to place of birth, firemen and "directors" being pooled because there is no statistical difference between them Three groups were made (1) those born in Helsinki and the surrounding county (Uusimaa), (2) those born in the four counties with the lowest mortality from cardiovascular disease among men aged 30–59 (fig 1), and (3) those born in the remaining counties or in the area ceded to the U S S R in 1940 and 1944—i e, Karelia

The mean serum-cholesterol levels of these groups are shown in table III No significant differences were found

TABLE III—MEAN TOTAL CHOLESTEROL (MG PER 100 ML) IN SERUM OF MEN IN HELSINKI CLASSIFIED BY AGE AND BY COUNTY OF BIRTH

Minneapolis	219±8·7 (18)	231±4·9 (74)	250±4·0 (103)	258±8·5 (28)

Numerals in parentheses denote number of men in group.

Thus it appears that the mean cholesterol differences between the population groups in East and West Finland are primarily determined by the mode of life and or other environmental factors. There are climatic differences between East and West Finland, but these are not great, both parts are subarctic with long cold winters and short cool summers.

The mean serum-cholesterol level appears to be somewhat related to the habitual level of physical activity among men aged 40–49. At older and at younger ages there were no statistically significant differences between activity groups, in the East the men in the less active occupations tended to have higher serum-cholesterol levels, while the reverse was true in the West, and neither of these trends is significant.

More detailed analysis will be made later as regards possible interrelations of serum-cholesterol levels with blood-pressure, relative obesity, body build, and electrocardiograms. The smoking history of the men is being analysed with the help of Dr. Esko Orma and Dr. Josef Brozek. So far it appears that, in all the groups, smokers tend to have higher serum-cholesterol levels than do non-smokers, but this relationship is not enough to explain the differences between the regions. The men in West Finland smoked less than those in the other groups.

TABLE V—MEAN LEVELS OF CHOLESTEROL (MG. PER 100 ML.) IN α-LIPOPROTEIN FRACTION OF SERUM IN MEN FOR WHOM TOTAL CHOLESTEROL AVERAGES ARE GIVEN IN TABLE II

Region and work grade	Age-group (yr.)			
	20–29	30–39	40–49	50–59
East, grades 1 and 2	41·8	46·3	46·0	45·7
,, 3 and 4	44·0	45·4	46·3	51·6
Helsinki directors	44·7	45·2	46·3	42·0
Helsinki firemen	46·2	45·3	45·9	46·8
West, grades 1 and 2	41·6	44·6	37·4	45·7
,, ,, 3 and 4	44·2	42·1	43·3	45·0

Other differences also were observed. The men in Helsinki tended to be tallest, those in East Finland shortest, and those in the West intermediate. Obesity was more common in the Helsinki groups than in the rural groups. Systolic blood-pressure tended to be highest in East Finland, lowest in Helsinki, and intermediate in West Finland.

Discussion

It is interesting to compare these findings in Finland with comparable studies in other populations. The averages at given ages are generally higher than in other populations studied by the same methods (Keys et al. 1957). Table IV compares men in the same occupation, full-time members of the city fire brigades in Helsinki, Malmö (Sweden), Naples (Italy), and Minneapolis (U.S.A.). Except at ages 20–29, where there is no significant difference between Helsinki and Minneapolis firemen, the Helsinki firemen have much higher serum-cholesterol levels than do the firemen in the other cities.

Similar differences between men of these populations appear when comparisons are made in other occupational categories (Keys et al. 1957). In general it seems that men in the populations studied in Finland have, on the average, higher total serum-cholesterol levels than do men studied elsewhere to date.

The differences in level of total cholesterol in the serum in the Finnish groups are due to cholesterol in the β-lipoprotein fraction separated by paper electrophoresis. Table v shows that the cholesterol level in the α-lipoprotein is substantially the same in all the groups, there are no statistically significant differences between any of the averages in table v.

The values for α-lipoprotein cholesterol in table v are comparable to those we have obtained in many other populations of men with both low and high serum-cholesterol levels and in dietary experiments in which the total serum-cholesterol level changed in response to alterations in the diet (Anderson et al. 1957, Keys et al. 1957). In clinically healthy men, at least, the levels of α-lipoprotein cholesterol show remarkably little variation, the mean values of groups and the means for many measurements on the same person seldom being outside the range of about 37–47 mg. per 100 ml. measured by our method.

TABLE VI—MEAN LEVELS OF α AND TOTAL CHOLESTEROL IN SERUM OF FARMERS' WIVES IN EAST AND WEST FINLAND

Group	α-cholesterol	Total cholesterol
20 East Finland women	56·2±3·5 (45·8)	237·7±12·2 (257)
28 West Finland women	56·7±1·6 (42·7)	227·0±7·5 (231)

Numerals in parentheses denote means for male farmers of same age in same area.

Women, however, usually have higher levels of α-lipoprotein cholesterol, though the level of total cholesterol in the serum tends to be similar to that for men of the same age in the same population. Data from East and West Finland (table VI) illustrate this point. Some farmers' wives accompanied their husbands and asked to be examined also. This was permitted for reasons of local public relations, and the serum-cholesterol levels of 48 women, aged 30–49, are summarised in table VI. The average levels of α-cholesterol in the serum in both East and West Finland are higher, and those of total cholesterol and, especially, β-lipoprotein cholesterol tend to be lower in women than in their husbands. The mean levels of β-cholesterol in the serum of men are 29·7 and 18·0 mg. per 100 ml. higher than in the women in East and West Finland respectively.

Summary

Statistics indicate unusually high mortality-rates and morbidity-rates in Finland as a whole, and in East Finland in particular, ascribed to coronary disease.

Total cholesterol and that in the α and β lipoprotein fractions were measured in 869 clinically healthy men aged 20–59 in the city of Helsinki and in two rural regions of Finland.

The total cholesterol levels tended to be higher than those observed in populations elsewhere, and this excess was accounted for by β-lipoprotein cholesterol.

Farmers' wives resembled the men in the rural areas as regards total chloesterol but had higher levels of α-lipoprotein cholesterol

In the age range 40–49 the men in occupations demanding heavy physical work had lower cholesterol levels than had the men in lighter work, but at other ages the cholesterol level appeared to be unrelated to habitual physical activity

Smokers tended to have higher cholesterol levels and lower blood-pressures than had non-smokers

At all ages and activity levels the men in East Finland tended to have higher levels of total cholesterol in their serum than had the men in West Finland, and this difference was entirely accounted for by β-lipoprotein cholesterol However, when the men in Helsinki were classified according to region of birth, there were no significant differences, suggesting that the regional differences are not due to hereditary influences

CONSULTANT PATHOLOGIST

CITY GENERAL HOSPITAL, SHEFFIELD

Teare (1957) and Latts et al (1956) found a higher prevalence of peptic ulcer in necropsies of emphysema patients than might be expected in the general population In Teare's cases, which were all coroner's necropsies, the ratio of observed to expected ulcers or scars was 51/35 5 In the cases of Latts et al the prevalence of ulcer was 27%, which is at least three or four times the expected figure In contrast to Teare's cases many of these patients died from emphysema, and it can be assumed that many of them had been severely anoxic with right-sided heart-failure Fulton (1953) found peptic ulceration at necropsy in 9 out of 50 cases of cor pulmonale, but neither Bockus (1944) nor White (1951) observed an increased prevalence of ulcer in heart-failure, though mucosal venous engorgement was common

Referring to the work of Latts et al *The Lancet* (1956) commented that it would perhaps be wise to await confirmation of the possible connection between peptic ulceration and hypertrophic pulmonary emphysema before speculating on the cause The present study, based on necropsy material at the City General Hospital, Sheffield, was designed to elicit further information concerning this relationship

TABLE I—PREVALENCE OF PEPTIC ULCER IN CONGESTIVE HEART FAILURE 88 CONSECUTIVE NECROPSIES

—	Cor pulmonale			Other cases of heart failure		
	Males	Females	Both sexes	Males	Females	Both sexes
No examined	19	5	24	33	31	64
Peptic ulcer	7	3	10	2	1	3

Prevalence of Peptic Ulceration in Heart-failure

Between March 17, 1952, and March 16, 1953, 88 patients with heart-failure were examined post mortem All had had congestive heart-failure and had been thoroughly investigated in life, especially with regard to the incidence of cor pulmonale (Flint 1954)

The high prevalence of active peptic ulceration discovered at necropsy in cases of cor pulmonale (10 out of 24), in all of which there had been anoxic heart-failure due to emphysema, contrasted with a prevalence of 3 in 64 other cases of heart-failure (table I) In the cases of cor pulmonale, the ulcers were acute and usually multiple in 5 (all duodenal), chronic in 3, and combined in 2 In the other forms of heart-failure, chronic ulceration was observed in 3 cases, acute ulceration was not seen

None of the 7 patients with acute ulceration had complained of pain, but 4 died after a massive hæmorrhage Only 2 had received an oral antibiotic

Prevalence of Acute Peptic Ulceration in Emphysema

The above figures suggested that further information might be gained from a postmortem study of acute peptic ulceration Arrangements were therefore made for a special scrutiny to exclude such a condition at all postmortem examinations on patients over the age of 16 for a period of twenty-four months—April 1, 1954, to March 31, 1956 At the end of this period the postmortem reports were reviewed and the original clinical notes studied in every case of acute ulcer, of chronic lung disease, and of heart-failure Of 87 cases of diffuse emphysema acute peptic ulceration was found in 18 (21%), and of the remaining 1037 cases without emphysema in 17 (1 6%) (table II) The prevalence was a little higher in patients with cor pulmonale, all of whom had exhibited congestive heart-failure in life (column 1), than in the emphysema patients without heart-failure (column 2), but many of the latter had been anoxic The ulceration was usually situated in the pyloric region of the stomach and multiple

In the emphysema group evidence of bleeding was found in 8 cases at necropsy and in 3 others in life In 1 patient the ulcer had perforated 4 patients had collapsed from unsuspected hæmorrhage None of the 18

TABLE II—PREVALENCE OF ACUTE PEPTIC ULCERATION IN 1124 CONSECUTIVE NECROPSIES

—	Emphysema cases					Remaining cases

No of cases examined	39	14	25	9	87	666	371	1037

* Site of ulceration in 18 emphysema cases duodenal 3 (single, 1, multiple 2), gastric 15 (single, 3, multiple, 12)

patients complained of ulcer dyspepsia, and an ulcer was suspected clinically in only 1 case

It can be assumed from a study of the clinical notes that all the patients with cor pulmonale had had profound hypoxia, hypercapnia, and acidosis, and most of them received treatment for a respiratory infection A tetracycline drug or chloramphenicol had been given orally to 9 of the 18 patients in whom acute ulceration was proved at necropsy, and to 27 of the 69 patients without ulceration It is therefore unlikely that the lesion had been caused by the irritant effect of the antibiotic on the gastric mucosa

Of 17 cases of acute ulcer not associated with emphysema, 5 were admitted to hospital because of bleeding In the remaining 12 cases, the following lesions were detected cerebral thrombosis (3), uræmia (2), mitral stenosis with heart-failure (3), lobar pneumonia (3), and hepatic cirrhosis (1)

An active chronic gastric or duodenal ulcer was found in 5 of the 87 emphysema patients

Discussion

In the first series here described, gastric and duodenal ulceration was detected at necropsy more frequently in patients who had died from cor pulmonale than in those who had died from other forms of heart-failure In the second series acute ulceration was found to be 13 times more frequent in cases of emphysema than in all the remaining cases submitted to necropsy

Most patients with emphysema had been severely anoxic—apparently because of respiratory infection Possible factors in the development of ulceration in cases of emphysema are (1) acute respiratory infection, (2) chronic respiratory infection, (3) drug toxicity, (4) derangement of the gaseous equilibrium of the blood, (5) a combination of these factors, (6) congestive heart-failure in combination with one or more of these factors, but not by itself, (7) the strain, mental and physical, of a long illness, (8) tobacco, dietary, and nutritional factors

An answer to this problem of ætiology has not been gained from the present survey In a controlled clinical investigation Allibone and Flint (1958) found that the prevalence of chronic bronchitis and of acute respiratory infection in patients admitted to hospital with acute perforation or hæmorrhage was similar to that for a control group of surgical emergencies, but only 2 patients had anoxic heart-failure Thus, the high incidence of peptic ulceration in emphysema is apparently restricted to fatal or severe cases The possible irritant effect of oral antibiotics can be discounted The factor common to all fatal cases of emphysema is the derangement of blood gases Browne and Vineberg (1932) showed that this could influence gastric secretion in animals, but knowledge of the influence of hypoxia and hypercapnia on human gastric secretion is lacking It is theoretically possible that this gaseous disturbance could either stimulate the secretion of gastric juice or impair the secretion of gastric mucus Experimental work in this field might yield useful information about the ætiology of peptic ulcer

Summary

88 patients with congestive heart-failure were examined post mortem Of 24 cases of cor pulmonale due to anoxic emphysema, 10 had peptic ulceration (7 acute), of 64 cases of heart-failure due to other causes, 3 had peptic ulceration (none acute)

In a second planned series of consecutive necropsies, which included all examinations in patients over 16 during a period of two years, there were 87 cases of severe emphysema (which in most cases was complicated by severe anoxia or pulmonary heart-failure) Acute ulceration was found in 18 (21%), against a prevalence of 17 (1 6%) in 1037 cases without emphysema

There appears to be a definite association between acute peptic ulceration and severe emphysema This may possibly be due to derangement of blood gases

We wish to thank our medical and surgical colleagues at the City General Hospital, Sheffield, for allowing us to peruse the case-notes of patients admitted under their care.

CITY GENERAL HOSPITAL, SHEFFIELD

Flint and Warrack (1958) report the prevalence of acute peptic ulcer in over 1000 consecutive hospital necropsies For cases of generalised emphysema the figure was 21%, compared with 1 6% for the remaining cases without emphysema In a separate series of 88 consecutive necropsies in cases of congestive cardiac failure, they found a higher prevalence of peptic ulceration in cases of anoxic cor pulmonale (10 out of 24) than in other cases of heart-failure (3 out of 64) A relatively high prevalence of peptic ulceration in emphysema at necropsy was also noted by Fulton (1953), Latts et al (1956), and Teare (1957)

Hurst and Stewart (1929), reviewing 151 cases of acute peptic ulcer, obtained a history of antecedent respiratory infection in 23% Many workers, dealing with large series of cases, have reported an increased prevalence of peptic ulcer and its complications in the winter months (Illingworth et al 1944, Jamieson 1947, 1955, Ivy et al 1950, Boles and Westerman 1954) It seemed therefore possible that the relatively high prevalence of peptic ulcer in fatal cases of emphysema might be attributable to the respiratory infection which is invariably present in these cases

To determine the significance of chronic bronchitis and acute respiratory infections in the ætiology of peptic ulcer, we questioned and examined a consecutive series of patients admitted to hospital with either gastrointestinal hæmorrhage or perforation A series of matched controls, admitted to hospital because of an acute surgical emergency, were similarly examined In addition we also attempted to assess other ætiological factors, including aspirin, alcohol, tobacco, mental stress, and certain drugs That aspirin was an important cause of gastric and duodenal hæmorrhage had been suggested by the work of Douthwaite (1938, 1954), Douthwaite and Lintott (1938), and Muir and Cossar (1955) This view, however,

TABLE I—AGE AND SEX DISTRIBUTION

—	Total	Males			Females		
		Under 45	45–64	Over 65	Under 45	45–64	Over 65
Hæmorrhage	100	13	36	13	4	19	15
Perforation	29	10	9	8	1	0	1

was challenged by the work of Paul (1943) and Wolf and Wolff (1943)

Material and Method

During the period December, 1956, to July, 1957, inclusive, 119 patients with acute gastric or duodenal hæmorrhage and 35 patients with acute gastric or duodenal perforation were admitted to the City General Hospital, Sheffield

Each patient was questioned by one of us as to symptoms of gastric disorder, chronic bronchitis, and acute respiratory infection starting within four weeks of admission to hospital, and then examined Each patient was also questioned about his consumption of aspirin, sulphonamides, oral antibiotics, alcohol, cortisone and adrenocorticotrophic hormone, phenylbutazone, and other medicines and tablets during the two weeks preceding hospital admission, and about any special strain or worry within four weeks This information, together with the clinical findings and the results of any investigations, which included radiography of the chest and stomach and, if necessary, gastroscopy, was recorded on a specially prepared form

TABLE II—CAUSES OF HÆMORRHAGE 100 CASES

—	*Males*	*Females*	Both sexes	Deaths
Peptic ulcer				
All cases	59	36	95	3
Acute	14	13	27	0
Chronic gastric	11	8	19	1
Chronic duodenopyloric	31	10	41	1
Chronic—site unknown	1	0	1	1
Hiatus hernia, œsophageal	0	4	4	0
Pyloric stenosis	2	1	3	0
Cancer of stomach	2	1	3	2
Œsophageal varices	0	0	0	0
Mucosal tear	1	1	2	0
Diffuse ooze	0	0	0	0
Total	62	38	100	5

Associated diseases hepatic cirrhosis, 4 cases, nephritis/uræmia, 1 case, cerebral thrombosis, 3 cases, lung cancer, 1 case, heart-failure, 1 case, tabetic crisis, 1 case

A control series of patients were also questioned and examined in a similar manner by the same observer, and the results recorded on the questionnaire These controls were patients admitted to hospital because of a confirmed non-thoracic surgical emergency or accident Gynæcological and maternity cases, together with patients who had symptoms of peptic ulcer, were, however, excluded Each case of hæmorrhage or perforation was matched against a control by selecting from the list of controls the first patient of the same sex, and within the same five-year age-group, who was admitted to hospital within the same two-week period

A matched control could not be found for 19 cases of hæmorrhage and 6 cases of perforation In all, 100 cases of hæmorrhage and 29 cases of perforation are analysed together with a similar number of matched controls Their age and sex distribution are set out in table I (those for the controls were similar), and the causes of bleeding and perforation in tables II and III

TABLE III—CAUSES OF PERFORATION 29 CASES OF PEPTIC ULCER

—	Males	Females	Both sexes	Deaths
Acute gastric or duodenal	6	0	6	0
Chronic gastric	2	0	2	1
Chronic duodenopyloric	19	2	21	1
Total	27	2	29	2

It will be seen from table II that in 95 of the 100 cases the cause of hæmorrhage was peptic ulceration, which in 27 cases was thought to be acute It is unlikely, however, that this latter figure is accurate as the distinction between an acute and chronic ulcer proved to be exceedingly difficult In 3 cases the hæmorrhage was from a cancer of the stomach, and in 2 patients, 1 of whom had a tabetic crisis, it was thought to come from a mucosal tear caused by excessive vomiting—a little-known but not uncommon cause described by Decker et al (1953) In each of the 4 cases of hepatic cirrhosis there was definite evidence of peptic ulceration of the stomach and in no instance was the bleeding from œsophageal varices

TABLE IV—PREVALENCE OF CHRONIC BRONCHITIS AND ACUTE RESPIRATORY INFECTIONS IN ALL CASES OF HÆMORRHAGE AND PERFORATION

—	*Males*		*Females*		*Both sexes*	
	Series	Controls	Series	Controls	Series	Controls
No of patients questioned	89	89	40	40	129	129
Acute respiratory infection (onset within 4 weeks)						
Total	35	29	18	13	53	42
Cold/sore throat	26	19	16	8	42	27
Cough and wheeze-acute bronchitis	9	10	2	5	11	15
Pneumonia	0	0	0	0	0	0
Chronic bronchitis/emphysema without heart-failure	14	24	3	5	17	29
Chronic bronchitis/emphysema with anoxic heart-failure	2	0	0	0	2	0

There were 5 deaths among the cases of hæmorrhage, which in 2 came from a gastric carcinoma A 3rd patient died from heart-failure due to anoxic pulmonary emphysema following emergency gastrectomy for recurrent bleeding, and a 4th patient died from cancer of the lung 18 patients were treated by emergency surgery, with 1 death

Of 29 patients with perforation, 27 were male and 2 female In 6 cases the ulcer was acute and in the duodenopyloric region, in 2 it was chronic and gastric, and in 21 chronic and duodenopyloric 27 patients were treated by simple surgical suture, and 1 by emergency gastrectomy There were 2 fatalities, both in men aged over 75

Acute Respiratory Infection and Chronic Bronchitis

The prevalence of acute respiratory infection and of chronic bronchitis in 129 cases of hæmatemesis or perforation is compared with the matched control series in table IV The prevalence of acute upper respiratory infection (53 out of 129) was not significantly higher than in the control series (42 out of 129), and the prevalence of chronic bronchitis, which was defined as chronic cough with wheeze or dyspnœa not due to heart-disease or other causes, was slightly higher in the controls Both in ulcer cases and in controls, chronic bronchitis was encountered more frequently in men than in women, and

TABLE V—PREVALENCE OF CHRONIC BRONCHITIS AND ACUTE RESPIRATORY INFECTIONS ACUTE ULCER AND OTHER CASES COMPARED

—	Acute ulcer	Controls	Other cases	Controls
No of patients questioned	33	33	96	96
Acute respiratory infection	13	12	40	30
Chronic/bronchitis emphysema	8	4	11	25

examine their patients, to Dr F Avery Jones and Dr Richard Doll for advice in planning the investigation, and to Miss Barbara White for statistical help

CONSULTANT ANÆSTHETISTS AT THE HOSPITAL FOR SICK CHILDREN, GREAT ORMOND STREET

Atresia of the œsophagus has been recognised for a long time, but the first successful attempt at anastomosis was made only sixteen years ago At the Hospital for Sick Children, Great Ormond Street, between October, 1953, and November, 1956, there were 54 cases, and 30 of the infants are still living

The incidence is hard to determine Fairlie (1954) reviewed the cases occurring over five years in Glasgow and obtained a figure of approximately 1 in 5000 births, but the estimate of Belsey (1950) was 1 in 800

Diagnosis

Early diagnosis, by the correct method, is of great importance Atresia of the œsophagus should be suspected in any newborn child in whom an excess of mucus and saliva persists in the mouth and pharynx If feeds have been attempted, there will be a history of cyanotic attacks and choking

Contrast material, of any kind, should never be used to establish the diagnosis, because of the risk of spreading it through the respiratory tract, adding to the mucus (and sometimes milk) already in the trachea and bronchi and thus causing respiratory obstruction An example of this is seen in the figure Of the 54 cases at this hospital 23 had been given contrast media before admission

To confirm the diagnosis, all that is necessary is to pass a soft rubber catheter through the mouth If the catheter is held up less than 4 inches from the gums, and if stomach contents cannot be withdrawn, atresia of the œsophagus is probably present

Types of Œsophageal Atresia

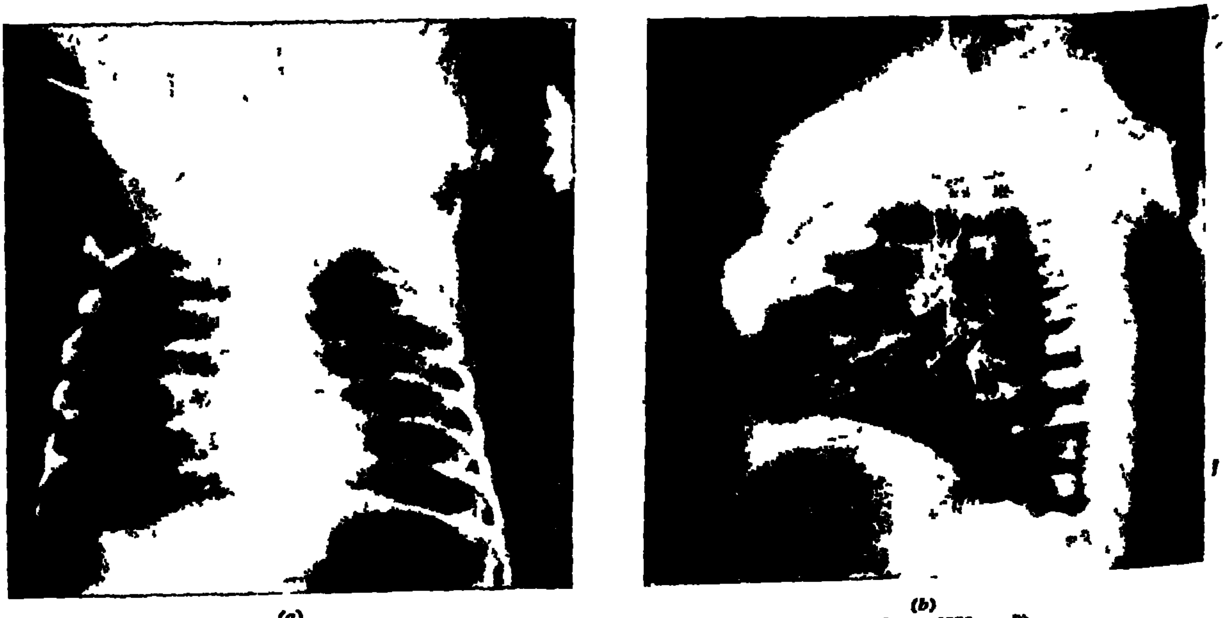
According to Waterston (1954) there are two main types, and three rare types

Main Types
- (*a*) Atresia with tracheo-œsophageal fistula into the lower segment of the œsophagus (90% of the cases)
- (*b*) Atresia without fistula (9% of the cases)

Rare Types
- (*a*) Atresia with tracheo-œsophageal fistula into both lower and upper segments of œsophagus
- (*b*) *Atresia with tracheo-œsophageal fistula into the upper segment of œsophagus*
- (*c*) Fistula without atresia

Association with Other Abnormalities

Œsophageal atresia is often associated with other congenital abnormalities, some of which may be incompatible with life for more than a few days In our series the commonest lesion was congenital heart-disease, which cannot always be diagnosed before operation These babies may appear normal in every way, with good colour, good tone, and normal heart sounds, yet at necropsy a grossly abnormal heart may be found Thus in case 39 the child died unexpectedly at the end of operation and was found to have transposition of the great vessels, infantile coarctation of the aorta, and ventricular and atrial septal defects, and there were several other cases in which heart-disease was detected



(*a*) (*b*)
(*a*) Before and (*b*) after coughing following instillation of iodised oil (ref *Anæsthesia*, 1958, no 2)

only at postmortem examination or when the patient was seen again later Furthermore, many of these cases have conditions such as rectal atresia or cleft palate, and in our series there have been infants with mongolism, hydrocephalus, agenesis of kidney, agenesis of lung, mucocolpos, and hæmangioma of liver

Of our 19 cases in which there were other major congenital defects, 14 died (tables I and II), whereas in the 35 uncomplicated cases there were only 10 deaths Thus the survival-rate was about 25% in the first group compared with about 70% in the second

Treatment

On admission to hospital the child's general condition is assessed, and the diagnosis is confirmed radiologically by passing a radio-opaque catheter into the upper pouch of the œsophagus The condition of the lungs can be seen in the same X-ray There is always collapse of the right upper lobe, and there may be patches of collapse throughout both lungs Often intercostal retraction is present, and breathing may be further embarrassed because of distension of the stomach by air sucked in through the fistula If the fistula is valvular, the stomach and intestines will overdistend with air, in which case operation is extremely urgent If the stomach is not distended, operation should be delayed for a few hours in order to

(i) Commence antibiotic treatment
(ii) Clear the air-passages as much as possible
(iii) Obtain compatible blood

Drainage of the trachea and bronchi is helped by a head-down tilt Only a soft rubber catheter should be used to suck out the pharynx and upper pouch, although the wall of the pouch is in fact hypertrophied and therefore difficult to perforate

TABLE II—MORTALITY IN RELATION TO OTHER ABNORMALITIES

Classification	No of cases	No of deaths	Mortality %
Tracheo-œsophageal fistula only or complicated by minor congenital abnormalities	31	9	29
Premature infants with tracheo-œsophageal fistula only or complicated by minor congenital abnormalities	4	1	25
Tracheo-œsophageal fistula complicated by major congenital abnormalities	13	8	61 5
Premature infants with tracheo-œsophageal fistula complicated by major congenital abnormalities	6	6	100
Total	54	24	44 4

TABLE I—SUMMARY OF CASES

Case	Age (days)	Birth-weight (lb oz)		Radio-opaque medium	Other congenital abnormalities	Relaxant	Immediate postoperative respiratory difficulty	Result
1	1			L		T	+ − +	Died
2	1	5	7	L		T	+ + −	Died
3	1			L		None	None	Survived
4	2	4	0	L	Rectal atresia	T	+ +	Died 5 days later, after gastrostomy

L = 'Lipiodol' D = 'Dionosil' B = barium T = tubocurarine S = suxamethonium. G = gallamine.
* In this case the operation was confined to tracheostomy and gastrostomy

Preoperative intravenous fluid is unnecessary, for the child is seldom dehydrated, but an intravenous drip (5% dextrose, preferably into the left arm) should be set up in the operating-theatre to facilitate administration of drugs, or blood, if required

Atropine 0 3 mg is given intramuscularly half an hour before operation This stops the flow of saliva, which may be inhaled, and also prevents the vagal slowing of the heart which may result from local surgical stimulation But if the secretions are viscid, atropine, by increasing their viscosity, may cause further obstruction to breathing, and is better avoided, though it may be given during the operation if the heart-rate slows unduly

The Anæsthetic Plan

Anæsthesia for œsophageal atresia must provide for a right thoracotomy and transpleural approach to the mediastinum, where, with the right lung collapsed, the upper and lower pouches of the œsophagus are identified, dissected out, and the two ends anastomosed Diathermy is used

To ensure oxygenation, and to permit removal of secretion from trachea and bronchi during operation, intubation of the trachea is necessary, and this is one of the most important details of the anæsthetic procedure

Surgery is possible after endotracheal intubation and nitrous-oxide/oxygen anæsthesia (10 cases, see table II) However, as the breathing of newborn infants is more diaphragmatic and abdominal than intercostal, each breath will draw the lower pouch down and away from the upper pouch, similarly swallowing will cause the upper pouch to move upwards and away from the lower pouch This constant movement and jerking of the diaphragm makes anastomosis difficult for the surgeon, who is already working in a small field A sound anastomosis is very important, because postoperative leaking causes mediastinitis

Perfect conditions may be obtained by the use of muscle relaxants Oxygenation is effected by controlled inflation of the left lung and the part of the right lung which is not completely collapsed by retractors Thus breathing may be modified to avoid interference with the operation

Choice of Relaxant

For some time at this hospital *d*-tubocurarine chloride was used, but recently we have found that with suxamethonium ('Scoline') there are fewer cases of respiratory difficulty or complications, immediate or delayed Of the 23 cases given suxamethonium, only 1 (case no 53) showed postoperative respiratory difficulty, and this was traced to a second tracheo-œsophageal fistula, whereas of the 18 cases given tubocurarine or gallamine 8 had postoperative respiratory trouble (table III) Stead (1955) showed that the newborn infant is far more resistant to depolarising agents than the adult, though the pseudo-cholinesterase level may be as low as 40%, and also that the inverse relation between sensitivity to depolarising agents and to competitive agents holds true Thus the newborn is very sensitive to tubocurarine, reacting in the same way as a myasthenic patient

The advantage of suxamethonium is that there is no danger of the patient remaining curarised after the operation The disadvantage is that its effect lasts so short a time that repeated injections must be made (Each injection tends to have a longer effect than the one before) With tubocurarine, on the other hand, no matter how small the dose, it is scarcely possible to ensure that the patient is not still curarised at the end of the operation, for reversal of its action by neostigmine does not seem to be reliable (Rees 1950) Unlike those of the adult, the limb movements of a partially curarised infant may appear vigorous, but they differ from the normal movements by their jerkiness

TABLE III—RELATION OF POSTOPERATIVE RESPIRATORY DIFFICULTY TO THE USE OF RELAXANTS

Relaxant used	No of cases	Cases showing postoperative respiratory difficulty	Percentage of cases
		Number	Percentage
Tubocurarine or gallamine	18	8	44
Suxamethonium	23	1	4
Unrecorded	2	1	
None	10	1	10

Anæsthetic Management

The first step in anæsthetising these patients is to ensure that they are well oxygenated Newborn infants have a high hæmoglobin—usually above 100%—which means that they will show cyanosis quickly

Oxygen alone is given for 2–3 minutes, after which laryngoscopy is carefully carried out on the conscious patient (M H and P M H) The contents of the pharynx and upper pouch of the œsophagus (secretions, milk, iodised oil) are removed by suction The fine gum elastic catheter used for this purpose may also be passed through the cords, sucking trachea and bronchi clear The smallest-size endotracheal tube is passed into the trachea As the average length of the trachea in the newborn is 4 cm, care must be taken not to pass the tube further than this through the cords A Cobb's connection is used so that suction of the trachea and bronchi is possible during operation

An alternative method of induction (R W C) is to give intravenous suxamethonium after a few breaths of oxygen, followed by laryngoscopy and careful suction of pharynx and trachea Intubation and suction are made easier by giving a relaxant first, but it is probably wiser to view the larynx before suxamethonium is injected Unless one has reasonable confidence in the intubation, the first method should be used, because it is difficult to inflate the lungs of these small patients with no tube in situ

Anæsthesia is maintained with equal amounts of oxygen and nitrous oxide, and intravenous suxamethonium is given intermittently The initial dose is 0 5 mg per lb body-weight and the length of time necessary to eliminate this is noted If it is short, as is usual, the next injection is 1 0 mg per lb, and this is repeated, as required, until the time between injections is found to be lengthening The dose is then decreased to 0 5 mg per lb or even less If possible the total dose should not exceed 50 mg The suxamethonium is diluted, with sterile water, to a strength of 5 mg per ml

If the intravenous infusion is not satisfactory, suxamethonium may be given in the same dosage intramuscularly—preferably with hyaluronidase, to ensure that all the drug is absorbed before the end of the operation Each injection by this route takes effect within 2 minutes and lasts for about 10 minutes

After induction, a nasal catheter (size 5), containing a fine polythene tube (size 2), is passed through the nose to the limit of the upper pouch This helps the surgeon to identify the pouch, and, when this is opened, the polythene tube is anchored and the rubber catheter removed Just before the final anastomosing stitches are inserted, the polythene tube is passed through the lower pouch into the stomach, where it remains for postoperative feeding purposes

Respirations are controlled throughout the operation, using a high flow of gases (3 litres oxygen and 3 litres nitrous oxide) with, or without (M H), a 12 oz or 8 oz Waters' canister containing soda-lime The pressure needed to inflate the lungs of the newborn is more than that required for an older child, partly because the smaller endotracheal tube has a higher resistance Elimination of carbon dioxide is assisted by the high flow of gases, by adequately controlled respiration, and by the use of the canister—the high flow of gases being the most important factor

The average newborn child requires about 25 c cm oxygen per minute (Smith 1951), and as the tidal air is approximately 20 c cm (Cross 1949), a rapid respiratory rate is needed Rates of up to 40 per minute are usual Rates exceeding this may diminish tidal exchange and embarrass venous return to the heart

With this technique the patient, at the end of operation, will be awake and crying, with a good colour, good muscle tone, and good movements of the chest wall

Difficulties

The first difficulty encountered during anæsthesia may be distension of the stomach with anæsthetic gases passing through the fistula, particularly if this is large (If the endotracheal tube itself passes through the fistula into the lower pouch, the stomach will be inflated but not the lungs) This difficulty can usually be overcome by altering the position of the tube, but, if not, the surgeon must be asked to close the fistula as quickly as possible Meanwhile, a hand pressed gently over the stomach will prevent overdistension, and permit inflation of the lungs When the fistula has been closed, the stomach may be emptied of gases by passing a catheter through the lower pouch

The pressure of the assistant's retractor may cause anxiety, for the trachea and bronchi are soft and easily compressed If a good colour can be maintained by inflation of the left lung, pressure on the right main bronchus does not matter, but usually this is not so, and the pressure of the retractor must be released Pressure over the pericardium can slow the heart and should be avoided

One of the main difficulties is estimation of the degree of shock The newborn infant may be apparently well only a short time before it is obviously moribund The various stages of shock are not easily recognisable as they are in the adult Assessment of the patient's condition is helped by strapping a small stethoscope over the heart. As in the fœtus, the onset of shock is indicated by slowing of the heart-rate The radial pulse disappears early, because of vasoconstriction in the limbs If any radial pulse can be felt, the condition is satisfactory, but its absence does not imply the degree of shock which would be expected in an adult undergoing thoracotomy

The length of the operation is important, for if the chest is open for more than 1¹/₂ hours the child's general condition will usually give rise to anxiety The use of relaxants, as described above, allows the surgeon to work under ideal conditions, using diathermy, and thus decreases operating-time

Usually, little blood is lost and its replacement may not be necessary However, as the blood-volume of the newborn is 40 ml per lb (making a total of only 200–300 ml), even a small loss must be replaced if shock is to be prevented A deficit of more than a tenth of the total volume should not be permitted, for infants tolerate blood-loss badly, and later replacement is not always successful If the loss cannot be measured, 10 ml of blood per lb body-weight may safely be given without overloading the circulation, but it is our practice to weigh the swabs and to replace the blood through a finely graduated drip chamber

The temperature of these patients always falls during operation, and to a certain extent this is a protective mechanism Temperatures may be as low as 86°F, though more often the reading is 88–89°F The patient should not be actively warmed, but further heat loss should be guarded against He will gradually regain the normal temperature, sometimes taking two or three days to do so, and the quicker he regains it the better will be his general condition This is still a controversial subject

When the operation is complete, the right lung is gently re-expanded If a thoracic drain is used, it is attached to an underwater seal as soon as the chest is closed The pharynx is carefully sucked out, and when the respirations are adequate, the endotracheal tube is removed

Postoperative Management

Constant skilled nursing attention, together with almost constant medical supervision, is essential during the first few postoperative days The airway must be kept clear of secretions, by repeated suction of mouth and pharynx The infant is nursed flat because of the danger of reflux gastric secretions reaching the site of the anastomosis when in the head-down position The secretions may be so viscid that suction is difficult 'Alevaire', a detergent, lowers the surface tension of the thick mucus, thus facilitating suction it is given by passing the oxygen over a solution of alevaire on its way to the box in which the infant is nursed Pulmonary collapse due to blocking of the bronchi by secretion can thus be prevented

This problem is complicated by abnormalities in the trachea itself There is a valve-like fold of mucous membrane lying over the fistula opening in the posterior wall of the trachea, as described by Franklin and Graham (1953) This fold may become œdematous after operation, causing further restriction of the airway Also, because of abnormality of its cartilaginous rings, the trachea may tend to collapse on inspiration If the airway is restricted in this way, the endotracheal tube may have to be replaced

As a routine, the chest is radiographed on the first postoperative day

Conclusions

What conclusions may be drawn, and what policy formulated, from this small and unselected series of 54 cases ?

Early recognition of the condition and early transfer to a unit accustomed to such cases, are major conditions of success Additional abnormalities diminish the likelihood of saving the child

Where the anæsthetist can tip the balance towards success seems to be in his choice of a relaxant technique giving ideal conditions to the surgeon and therefore shortening the operating-time Of the relaxants, succinylcholine is preferable to tubocurarine or gallamine, because its use is much less often followed by postoperative difficulties in respiration Success depends not only on the main lines of policy but also on attention to the minutiæ of technique

We gratefully acknowledge permission to describe this series of cases, all of which were treated by the surgical consultant staff at the Hospital for Sick Children, Great Ormond Street To all our anæsthetic colleagues, we also express our sincere thanks for their kindly cooperation

STAPHYLOCOCCAL INFECTION IN MOTHERS AND INFANTS

MATERNAL BREAST ABSCESSES AND ANTECEDENT NEONATAL SEPSIS

From the Departments of Pædiatrics and Microbiology, University of Otago Medical School, and Dunedin Hospital, New Zealand

ANTIBIOTIC-RESISTANT strains of staphylococci are now firmly entrenched and widely distributed in New Zealand Most epidemics and sporadic infections have been caused by a staphylococcus of relatively high drug resistance, of the phage-type 80/81, the type of organism closely studied by Rountree (1955) in Australian maternity infections One serious maternity hospital epidemic with a high mortality-rate has occurred (Beaven and Burry 1956, Douglas and Knights 1956) and less serious and smaller epidemics have arisen throughout the country Early in 1957 the number of patients admitted to a general hospital for treatment of breast abscesses during lactation reached serious proportions (15 cases in four months), whereas, in the preceding fifteen years (annual birth-rate of 1500 to 2300) only 4 to 6 cases were admitted each year When it was found that several of these women had been delivered in one maternity hospital (Hospital B), an investigation was instituted, and techniques were revised to control the epidemic and prevent further introduction and spread of infection

The relationship of maternal breast abscess, neonatal sepsis, and staphylococcal carriage in staff, mothers, and infants was also studied

A further outbreak in a smaller institution was also investigated The results of these investigations and the methods used to control the outbreaks are reported below

Material and Methods

Maternal Breast Abscesses

37 cases of maternal breast abscess, developing in the weeks following childbirth, are known to have followed confinement in maternity homes in this city in the past twelve months 31 of these required hospital admission for incision and drainage, and in 32 cases bacteriological investigations were carried out Information was obtained concerning the length of the time between delivery and onset, relationship to lactation, cracked nipples, infection in the infant, and place of delivery In 12 cases, additional information was available from the mother's nose and/or breast milk, and the infant's nose and/or lesion, as well as from the abscess Breast milk from 33 women (11 with abscesses and 22 normal), was examined for staphylococci

Buildings

Bacteriological investigations were carried out in Hospital B, a maternity unit of 44 beds, attached to Hospital A, an acute general hospital which serves a population of about 100,000, and a subsidiary investigation was carried out in a smaller " open " maternity home (Hospital C) of 20 beds where women are attended by their own practitioners

Hospital B is a three-storey concrete building, adjacent to Hospital A but with a separate staff It is of modern construction and is designed for efficient cleaning and dust control The patients are accommodated in single, double, and four-bed wards, and there are two large air-conditioned nurseries, an air-conditioned room for premature infants, and an isolation-room for the segregation of infected infants

Hospital C is a single-storey brick building which was not originally designed for maternity work and is older than Hospital B It contains 4 four-bed wards, 2 single, and 1 double room, and 2 rather small nurseries Because of the *difference in the design and state of the fabric of the two* buildings, efficient cleaning is more difficult in Hospital C than in Hospital B

In both institutions, dust and air samples were collected and examined for pathogenic staphylococci Dust was collected on moistened, serum-impregnated, cotton-wool swabs, and air was cultured by means of the slit-sampler, at the rate of 5 c ft. of air to one blood-agar plate in a five-minute period

Neonatal Sepsis

In Hospital B, in the first four months of 1957, while not all " sticky eyes " or minor skin lesions were swabbed, bacteriological data were available on septic skin lesions from 26 of the 232 infants born alive in that period After the introduction of special control measures in April, every suspected staphylococcal lesion in the infants was swabbed for bacteriological examination In the six months May to October, 1957, 52 (13%) of the 402 infants born alive were swabbed These included 25 skin lesions and 21 cases of " sticky eye " In unselected cases, swabs were taken from the nose and umbilicus of the infant, as well as from the lesion, and also samples from the mother's breast milk

Nasal Carriage of Staphylococci

The nasal carriage-rate was investigated in nursing and other staff of Hospital B in January, May, and September, and in Hospital C in September

With the help of three senior students (Burkinshaw, Hamer, and Swier 1957), 113 consecutive mother and infant pairs were swabbed The mothers were swabbed within twenty-four hours of admission, and again on the tenth day of the puerperium, and the infants on the fourth and tenth day of life 19 mothers in Hospital C and 22 infants in that home on a given day were swabbed

Bacteriology

Specimens of exudate, or nasal swabs, were collected on sterile serum-impregnated swabs, and primary culture was made on to blood-agar plates Colonies of staphylococci were subcultured into nutrient broth and tested for coagulase activity by the method of Fisk Strains showing coagulase activity, which was taken as an indication of pathogenicity, were tested for antibiotic sensitivity by a disc method Six-hour nutrient-broth cultures were subcultured on to nutrient-agar plates in such a way that a peripheral zone of the plate, 2 cm. wide, was sown with the test organism Discs impregnated with various antibiotics (penicillin 3 units, streptomycin 66 µg , chlortetracycline (aureomycin) 20 µg , chloramphenicol 20 µg , oxytetracycline (terramycin) 20 µg per ml) were placed along the inner edge of the cultured zone Each disc was controlled by making radiating streak cultures of the Oxford strain of staphylococcus from the centre of the plate to each disc. A zone of inhibition of the test organism equal to at least half that shown by the control staphylococcus was taken as indicating that the test organism was sensitive to the antibiotic concerned

Methods of Control

When the "epidemic strain" of staphylococcus had been determined the following measures were taken to control its further spread and to attempt its elimination from the hospital

Nasal swabs of all Hospital B staff (nursing, medical, cleaning, and clerical) were taken and carriers of the "epidemic strain" were put off duty and treated with local application of 1% chlorhexidine ('Hibitane') cream or neomycin-bacitracin ointment until free of contamination.

Any infant with clinical sepsis was isolated, either by "rooming in" with the mother or in the isolation nursery Barrier nursing was applied and bacteriological investigations were made. Gowns and masks were worn in the nurseries at all times, and hexachlorophene (G11) soap and 1% chlorhexidine hand-cream were used routinely before and after infant handling Disposable towels continued in use The bathing of babies was discontinued, they were oiled after birth and cot-treated thereafter until discharge on the twelfth to fourteenth day

The heating and ventilating plant was overhauled One plant, which was removing dusty air from a nursery and returning it to the premature nursery, was converted to the "plenum" system for both rooms Blinds and curtains in the nurseries are being replaced by external blinds

TABLE I—PHAGE-TYPES OF STAPHYLOCOCCI ISOLATED FROM 33 MATERNAL BREAST ABSCESSES

* Sulphonamides penicillin streptomycin chlortetracycline (aureomycin), chloramphenicol oxytetracycline (terramycin)
— = sensitive, — = resistant, = = moderately sensitive.

All bedding was sent to the laundry when mother and infant were discharged Cotton articles were washed and steam-pressed, which effectively sterilised them, and blankets were washed and treated with 'Lissapol' and 'Cirrasol' (Blowers and Wallace 1955)

The midwife admitting a mother asked for a family or personal history of recent sepsis A nursery record of all infections was started, and measures were taken to avoid overcrowding as far as was possible in a public institution which has to admit obstetric emergencies on request.

The umbilicus of each infant was dressed daily with alcohol The use of a binder (until the cord separated) was continued, since the results of swabbing were such that no change in technique was considered necessary Circumcisions were discontinued while there was any risk of nursery infection The routine instillation of sulphacetamide drops into the eyes of each newborn infant was stopped, and instead the eyelids were wiped with sterile saline-soaked cotton-wool

TABLE II—DISTRIBUTION OF BREAST ABSCESS CASES AND THEIR PHAGE-TYPES

—	No from Hospital B	Hospital C	Other homes	Total
No of cases swabbed	15	12	6	33
No coagulase-positive	15	11	6	32
No of 80 81 strains	10	9	5	24
No of 3B 3C 55 strains	1	0	1	2

Methods of Treatment

In addition to isolation, each infected infant received local treatment for the lesion

10% sulphacetamide was given for conjunctivitis and 1% gentian violet for pustules, if the infant remained well Systemic antibiotics, as indicated by the antibiotic-sensitivity tests, were reserved for cases of severe paronychia, furuncles, or abscesses In most cases chloramphenicol was used and no reactions were observed Any child who was toxic was transferred to the children's ward of the main hospital Only 1 transfer was necessary in over 50 cases in eight months Any lesion containing pus was incised.

Results

Maternal Breast Abscesses

Coagulase-positive staphylococci were obtained from 31 of 32 cases investigated 24 strains were identified as phage-type 80,81, and 21 of these had a characteristic antibiotic-sensitivity pattern (table I)

Time of onset—23 of the 33 abscesses developed between two and four weeks after confinement, 2 as late as twelve and fourteen weeks No relationship in time to any significant change or event in lactation has been discovered

Mode of onset—27 patients out of 29 gave a history of cracked nipples in the mother or infection in the infant, or both In the 29 patients interrogated, the abscess developed after an infection in the infant on 25 occasions, and after a cracked nipple in 14 In 11 there had been both an infection and a cracked nipple Many of these infants were unfortunately not available for detailed bacteriological investigation by the time the mother was seen in hospital 9 mothers are known to have had septic skin lesions which developed after confinement and before the abscess

Antibiotics had been given to 22 patients, but failed to cure the lesion and in no case did antibiotics cure once a mass had formed

16 patients required incision on two or more occasions and both breasts were affected in 5 The stay in hospital varied from three days to over six weeks (including readmissions), the majority of patients needed one to three weeks' hospital treatment.

The source of the cases and the bacteriological findings are shown in table II The 15 patients from Hospital B had been delivered in a six months' period, giving an abscess rate of 4% of confinements 9 of the Hospital C patients were delivered in a period of four months, a rate of 5% of confinements

Table III gives the results of groups of swabs taken from the same case (the maternal nose, breast milk, infant's nose, and/or lesion) While the strain of organism isolated from the abscess was isolated from the mother's nose on only 2 out of 12 occasions, the "abscess strain" was carried by the infant in almost all the cases studied

TABLE III—COMPARISON OF STAPHYLOCOCCI OBTAINED FROM THE NOSE AND BREAST MILK OF THE MOTHER, AND THE NOSE AND LESION OF THE INFANT, WITH THOSE FROM THE MATERNAL BREAST ABSCESS

—	Maternal nose	Maternal milk	Infant's nose	Infant's lesion
No swabbed	12	11	11	12
No of coagulase-positive swabs	2	6	9	11
Same phage-type as abscess in	2	5	9	11

TABLE IV—SKIN-SEPSIS RATES IN HOSPITAL B BEFORE AND AFTER INTRODUCTION OF CONTROL MEASURES

No of	January–April		May–October	
Live births	232		402	
—	No	% live births	No	% live births
Skin lesions swabbed	26	11	25	6
Coagulase-positive swabs	23	10	15	3 5
80/81 strain	13	6	3	0 7

Breast milk—The "abscess strain" of staphylococcus was isolated from the breast milk in almost half the cases examined 32 samples of breast milk were also obtained from 16 mothers in Hospital B who showed no sign of infection, but whose infant carried or was infected with staphylococci 7 mothers carried the same strain in the milk as that isolated previously from the infant, thus, as in the abscess series, almost half the patients yielded infected milk In 33 cases examined in Hospital B we have not found staphylococci in the breast milk of a woman whose child had a negative nasal swab

Infant Sepsis

In the four months before the introduction of the new nursing techniques in Hospital B, at least 11% (some lesions were not swabbed) of the 232 infants born alive had staphylococcal skin lesions 13 swabs grew staphylococci of phage-type 80/81 In the six months after the application of the new techniques the proportion of infants with staphylococcal skin lesions fell to 6% of 402 live births, organisms of phage-type 80/81 being found in only 3 infants The details of the infant-sepsis rate during the two periods are set out in table IV

Table V analyses the type of lesion and the results of bacteriological examination Only 6 out of 20 "sticky eyes" and 4 out of 12 pustules produced coagulase-positive staphylococci, whereas all cases of paronychia were caused by this organism

The nose and lesion of an infant were swabbed at the same time on 11 occasions, 5 of these pairs grew coagulase-positive staphylococci from both swabs, and in 4 the identical organism was present in both nose and lesion

Umbilical sepsis—No frank examples of umbilical sepsis were encountered during the period of this study 14 umbilical swabs were examined for various reasons and when bacteriological culture was carried out it was found that in only 3 cases were coagulase-positive staphylococci present, while 3 others carried *Escherichia coli* From the remaining 8 swabs either coagulase-negative staphylococci were obtained or there was no growth

Nasal Carriage by Staff

The incidence of coagulase-positive staphylococci in the nose of staff personnel is shown in table VI The variation in numbers of Hospital B staff swabbed is du to the inclusion of cleaning and domestic staff in the latter two surveys and to the presence of a new class of trainee nurses in September

While the proportion carrying coagulase-positive staphylococci (positive carriers) varied from 22% to 48 the proportion of penicillin-resistant staphylococ remained about 70% Similar figures were obtained fro the medical staff The single carrier of type 80/ (among the nursing staff) in September was a "persiste carrier", first identified in January as the probable sour of the 80/81 strain in Hospital B nursery infections

41 of the Hospital B staff (nursing, cleaning, and domesti were present for both the May and September surveys 20 these were non-carriers on both occasions 11 who we positive in May had become negative by September, whi only 2 non-carriers in May were positive in September were positive on both occasions, 4 of them carrying the sa or a closely related strain (as shown by phage-typing an sensitivity pattern) on both occasions

One pædiatrician who visited Hospital B weekly ha exchanged a penicillin-sensitive strain that was untypable i May, for a highly resistant strain, phage-type 80/81 in September This was almost certainly acquired from the children' ward of the hospital, where cases of staphylococcal empyem due to the phage-type 80/81 were under his care

TABLE V—TYPE OF LESION AND BACTERIOLOGICAL RESULTS (I SIX-MONTH PERIOD WITH 402 LIVE BIRTHS)

—	Lesion					
	"Sticky eyes"	Skin				Tot ski
		Pustules	Blisters	Scabs	Paronychia	
No swabbed	20	12	4	2	7	25
No producing coagulase-positive staphylococci	6	4	3	2	7	16
No producing coagulase-negative staphylococci	9	7	1	0	0	8
Other organisms	1	0	0	0	0	0
No growth	4	1	0	0	0	1

Nasal Carriage by Mothers and Infants

In Hospital B only 2 women of the 113 examine carried the 80/81 strain on admission, and 1 had lost i by the tenth day The overall maternal carriage rate o coagulase-positive staphylococci was 30% to 36%, but in this group the incidence of penicillin-resistant strains wa half that of the nurses or infants The small group of 1 mothers in Hospital C gave a similar figure (30%) 41% of the 22 infants in Hospital C were carriers at the tim

TABLE VI—NASAL CARRIAGE OF COAGULASE-POSITIVE STAPHYLOCOCCI

—	Source of swab		No of swabs	No coagulase-positive	% coagulase-positive	No penicillin resistant	% penicillin resistant	No. of 80/81 strain
Hospital B	Staff (nurses only)	January	36	8	22	5	63	2

of examination, but since their ages varied from a few hours to fourteen days, this is a lower figure than would have been obtained by swabbing each of these infants in its second week of life

Dust and Air

No coagulase-positive staphylococci were isolated from the samples taken from the nurseries and theatres in Hospital B, although much dust and a variety of organisms were obtained from various sources In the older institution (Hospital C), however, 9 of 43 specimens were positive, 2 being identified as type 80/81 (table VI)

Discussion

Since the description in Australia, by Rountree and Freeman (1955), of a newly identified strain of staphylococcus, the phage-type 80 or 80/81, this strain has now been identified in over 40 epidemics in many parts of the world (Shaffer 1957) Since it was first identified in New Zealand as a phage 52A variant (Battersby and Stringer 1954) and subsequently typed (weakly) as 42E/7/73 (Beaven and Burry 1956), Shaffer (1957) has shown the identity of the type 80 or 80/81 with the Canadian strain V-81, and his 42B/47C/44A/52/80/81 strain in the U S A This strain appears to show a predilection for maternity homes (Markham and Shott 1958)

The presence of a particular strain of staphylococci in maternity hospitals is an interesting and as yet unsolved problem It does appear, however, that the type 80/81 and certain other strains of staphylococcus find the environment of a maternity home particularly well suited to their propagation It has been suggested by Rountree and Freeman (1955) and Gillespie and Alder (1957) that this strain was of exceptional virulence, but in view of the frequency with which it occurred in minor lesions and the comparative rarity of severe complications, the property of "exceptional" virulence cannot be attributed to the organism seen here

It is now accepted (Rountree et al 1956) that breast abscesses during lactation are almost invariably due to staphylococci acquired in the maternity home, often from an infected infant, and our survey confirms these findings Thus the control of an epidemic of breast abscesses involves the control of neonatal infection in the maternity home Further, since asymptomatic carriage of staphylococci seems to be almost as dangerous (both for mother and infant) as frank sepsis, nasal carriage of staphylococci by the infants is of importance It was gratifying to find that the nasal carriage of all coagulase-positive staphylococci by the infants was reduced to under 40% by the measures described This figure compares most favourably with those quoted by Gairdner (1954) and others

Duncan and Walker (1942) showed that staphylococci were common in maternal milk, and they found that these organisms were derived from the infant's nose or throat (which was colonised first) and not from the mother's nose It appeared to us that the importance of breast milk in the transmission of staphylococci had not been fully appreciated, and this view has been confirmed independently by Wysham (1957)

In a maternity home, where dust and aerial contamination is common, a woman with cracked nipples appears to be at a considerable risk regardless of the state of her infant This may well have been the explanation of 4 of the Hospital C patients, none of whom carried staphylococci in their milk, but who, 2 or 3 at a time, had all been in one four-bed ward Milk may be much more important as a vector in a unit such as Hospital B where cleaning is effective and dust and aerial contamination in the wards slight or absent Under such conditions, the train of events in the production of a breast abscess may be introduction by a staff carrier, transfer to infant by hand or aerial spread, transfer from infant to infant in the nursery by hand or air, from infant to maternal milk, whence, in the presence of engorgement (of all or a part of the breast) or cracked nipples, an abscess develops

The technique of antenatal expression of colostrum advocated by Waller (1946) is recommended to all women attending the antenatal clinic of Hospital B, and only 3 out of 24 patients with breast abscesses had practised this exercise The benefits of this expression may not only be easier and more effective lactation but also, through improved function of the duct system of the breast, at least some degree of protection against abscess formation The periodical examination of samples of bulk breast milk from a maternity home may be a valuable screening procedure since, if a sample produces coagulase-positive staphylococci, a search may be made for the woman responsible It has also been valuable to culture the milk of the patient in any case of pyrexia of unknown origin in the puerperium

Williams (1956) described three types of neonatal sepsis staphylococcal infections of one phage-type from a single source (such as a nurse with boils), infections due to staphylococci which are of one type but are widespread in the environment, and infections by several phage-types which are similar to those carried by the nurses This last group he considers, is due to inadequate techniques It seems that these are not mutually exclusive and that the first, if not rapidly controlled, would lead to the second The experience in Hospital B corresponds closely to Williams' first group, since the sudden appearance of an epidemic of breast abscesses suggested that a new organism especially well adapted for survival in a maternity hospital had been introduced When this possibility was examined in Hospital B, it was found that one of the nursing staff not only carried organisms of the 80/81 strain in the nose but had suffered from recurrent boils caused by the same organism, and, since McDonald and Timbury (1957) have suggested that staphylococci from subacute infections are more pathogenic than those from a healthy mucous membrane, this may explain the sudden increase in infections The removal of this nurse from duty was the beginning of the end of this particular epidemic, and in the following six months there was only one breast abscess among the Hospital B patients, and this was due to a different phage-type

In contrast, Hospital C, the older building, which was more difficult to clean adequately, had an outbreak of the second type with contamination of dust and air

In Hospital B, the eradication of staff carriers of the epidemic strain, plus the introduction of new nursery techniques to reduce cross-infection, was effective in controlling the outbreak due to the 80/81 strain and also in reducing the "residual" sepsis of Williams' third group

Most infants born in Hospital B were seen by one of us (J A M) at a follow-up clinic, at the age of six to eight weeks, and, while some who had been free of infection in Hospital B had developed pustules or conjunctivitis after discharge, almost all infants appeared to clear up spontaneously by the age of two months, regardless of treatment

During the ten months of the survey only 1 infant had to be transferred from Hospital B to the children's ward of the general hospital This child progressed from crops of pustules to a massive subcutaneous abscess of the forearm No case of staphylococcal pyopneumothorax was seen from Hospital B, though 9 cases (with 4 deaths) were admitted to the children's ward of the hospital during the period These cases, which show the danger of staphylococcal complications, closely resemble those described by Beaven and Burry (1955) and Briggs (1957)

Our methods of treatment and control correspond closely with those advocated in the monograph of the

TABLE IV—SKIN-SEPSIS RATES IN HOSPITAL B BEFORE AND AFTER INTRODUCTION OF CONTROL MEASURES

No of	January–April		May–October	
Live births	232		402	
—	No	% live births	No	% live births
Skin lesions swabbed	26	11	25	6
Coagulase-positive swabs	23	10	15	3·5
80/81 strain	13	6	3	0·7

Breast milk—The "abscess strain" of staphylococcus was isolated from the breast milk in almost half the cases examined 32 samples of breast milk were also obtained from 16 mothers in Hospital B who showed no sign of infection, but whose infant carried or was infected with staphylococci 7 mothers carried the same strain in the milk as that isolated previously from the infant, thus, as in the abscess series, almost half the patients yielded infected milk In 33 cases examined in Hospital B we have not found staphylococci in the breast milk of a woman whose child had a negative nasal swab

Infant Sepsis

In the four months before the introduction of the new nursing techniques in Hospital B, at least 11% (some lesions were not swabbed) of the 232 infants born alive had staphylococcal skin lesions 13 swabs grew staphylococci of phage-type 80/81 In the six months after the application of the new techniques the proportion of infants with staphylococcal skin lesions fell to 6% of 402 live births, organisms of phage-type 80/81 being found in only 3 infants The details of the infant-sepsis rate during the two periods are set out in table IV

Table V analyses the type of lesion and the results of bacteriological examination Only 6 out of 20 "sticky eyes" and 4 out of 12 pustules produced coagulase-positive staphylococci, whereas all cases of paronychia were caused by this organism

The nose and lesion of an infant were swabbed at the same time on 11 occasions, 5 of these pairs grew coagulase-positive staphylococci from both swabs, and in 4 the identical organism was present in both nose and lesion

Umbilical sepsis—No frank examples of umbilical sepsis were encountered during the period of this study 14 umbilical swabs were examined for various reasons and when bacteriological culture was carried out it was found that in only 3 cases were coagulase-positive staphylococci present, while 3 others carried *Escherichia coli* From the remaining 8 swabs either coagulase-negative staphylococci were obtained or there was no growth

Nasal Carriage by Staff

The incidence of coagulase-positive staphylococci in the nose of staff personnel is shown in table VI The variation in numbers of Hospital B staff swabbed is due to the inclusion of cleaning and domestic staff in the latter two surveys and to the presence of a new class of trainee nurses in September

While the proportion carrying coagulase-positive staphylococci (positive carriers) varied from 22% to 48%, the proportion of penicillin-resistant staphylococci remained about 70% Similar figures were obtained from the medical staff The single carrier of type 80/81 (among the nursing staff) in September was a "persistent carrier", first identified in January as the probable source of the 80/81 strain in Hospital B nursery infections

41 of the Hospital B staff (nursing, cleaning, and domestic) were present for both the May and September surveys 20 of these were non-carriers on both occasions 11 who were positive in May had become negative by September, while only 2 non-carriers in May were positive in September 8 were positive on both occasions, 4 of them carrying the same or a closely related strain (as shown by phage-typing and sensitivity pattern) on both occasions

TABLE V—TYPE OF LESION AND BACTERIOLOGICAL RESULTS (IN A SIX-MONTH PERIOD WITH 402 LIVE BIRTHS)

—	Lesion					
	'Sticky eyes'	Skin				
		Pustules	Blisters	Scabs	Paronychia	Total skin
No swabbed	20	12	4	2	7	25
No producing coagulase-positive staphylococci	6	4	3	2	7	16
No producing coagulase-negative staphylococci	9	7	1	0	0	8
Other organisms	1	0	0	0	0	0
No growth	4	1	0	0	0	1

One pædiatrician who visited Hospital B weekly had exchanged a penicillin-sensitive strain that was untypable in May, for a highly resistant strain, phage-type 80/81 in September This was almost certainly acquired from the children's ward of the hospital, where cases of staphylococcal empyema due to the phage-type 80/81 were under his care

Nasal Carriage by Mothers and Infants

In Hospital B only 2 women of the 113 examined carried the 80/81 strain on admission, and 1 had lost it by the tenth day The overall maternal carriage rate of coagulase-positive staphylococci was 30% to 36%, but in this group the incidence of penicillin-resistant strains was half that of the nurses or infants The small group of 19 mothers in Hospital C gave a similar figure (30%) 41% of the 22 infants in Hospital C were carriers at the time

TABLE VI—NASAL CARRIAGE OF COAGULASE-POSITIVE STAPHYLOCOCCI

—	Source of swab		No of swabs	No coagulase-positive	% coagulase-positive	No penicillin resistant	% penicillin resistant	No. of 80/81 strain
Hospital B	Staff (nurses only)	January	36	8	22	5	63	2

of examination, but since their ages varied from a few hours to fourteen days, this is a lower figure than would have been obtained by swabbing each of these infants in its second week of life

Dust and Air

No coagulase-positive staphylococci were isolated from the samples taken from the nurseries and theatres in Hospital B, although much dust and a variety of organisms were obtained from various sources In the older institution (Hospital C), however, 9 of 43 specimens were positive, 2 being identified as type 80/81 (table VI)

Discussion

Since the description in Australia, by Rountree and Freeman (1955), of a newly identified strain of staphylococcus, the phage-type 80 or 80/81, this strain has now been identified in over 40 epidemics in many parts of the world (Shaffer 1957) Since it was first identified in New Zealand as a phage 52A variant (Battersby and Stringer 1954) and subsequently typed (weakly) as 42E/7/73 (Beaven and Burry 1956), Shaffer (1957) has shown the identity of the type 80 or 80/81 with the Canadian strain V-81, and his 42B/47C/44A/52/80/81 strain in the U S A This strain appears to show a predilection for maternity homes (Markham and Shott 1958)

The presence of a particular strain of staphylococci in maternity hospitals is an interesting and as yet unsolved problem. It does appear, however, that the type 80/81 and certain other strains of staphylococcus find the environment of a maternity home particularly well suited to their propagation It has been suggested by Rountree and Freeman (1955) and Gillespie and Alder (1957) that this strain was of exceptional virulence, but in view of the frequency with which it occurred in minor lesions and the comparative rarity of severe complications, the property of “ exceptional ” virulence cannot be attributed to the organism seen here

It is now accepted (Rountree et al 1956) that breast abscesses during lactation are almost invariably due to staphylococci acquired in the maternity home, often from an infected infant, and our survey confirms these findings Thus the control of an epidemic of breast abscesses involves the control of neonatal infection in the maternity home Further, since asymptomatic carriage of staphylococci seems to be almost as dangerous (both for mother and infant) as frank sepsis, nasal carriage of staphylococci by the infants is of importance It was gratifying to find that the nasal carriage of all coagulase-positive staphylococci by the infants was reduced to under 40% by the measures described. This figure compares most favourably with those quoted by Gairdner (1954) and others

Duncan and Walker (1942) showed that staphylococci were common in maternal milk, and they found that these organisms were derived from the infant's nose or throat (which was colonised first) and not from the mother's nose. It appeared to us that the importance of breast milk in the transmission of staphylococci had not been fully appreciated, and this view has been confirmed independently by Wysham (1957)

In a maternity home, where dust and aerial contamination is common, a woman with cracked nipples appears to be at a considerable risk regardless of the state of her infant This may well have been the explanation of 4 of the Hospital C patients, none of whom carried staphylococci in their milk, but who, 2 or 3 at a time, had all been in one four-bed ward Milk may be much more important as a vector in a unit such as Hospital B where cleaning is effective and dust and aerial contamination in the wards slight or absent Under such conditions the train of events in the production of a breast abscess may be introduction by a staff carrier, transfer to infant by hand or aerial spread, transfer from infant to infant in the nursery by hand or air, from infant to maternal milk, whence, in the presence of engorgement (of all or a part of the breast) or cracked nipples, an abscess develops

The technique of antenatal expression of colostrum advocated by Waller (1946) is recommended to all women attending the antenatal clinic of Hospital B, and only 3 out of 24 patients with breast abscesses had practised this exercise. The benefits of this expression may not only be easier and more effective lactation but also, through improved function of the duct system of the breast, at least some degree of protection against abscess formation The periodical examination of samples of bulk breast milk from a maternity home may be a valuable screening procedure since, if a sample produces coagulase-positive staphylococci, a search may be made for the woman responsible. It has also been valuable to culture the milk of the patient in any case of pyrexia of unknown origin in the puerperium

Williams (1956) described three types of neonatal sepsis staphylococcal infections of one phage-type from a single source (such as a nurse with boils), infections due to staphylococci which are of one type but are widespread in the environment, and infections by several phage-types which are similar to those carried by the nurses This last group he considers, is due to inadequate techniques It seems that these are not mutually exclusive and that the first, if not rapidly controlled, would lead to the second The experience in Hospital B corresponds closely to Williams' first group, since the sudden appearance of an epidemic of breast abscesses suggested that a new organism especially well adapted for survival in a maternity hospital had been introduced When this possibility was examined in Hospital B, it was found that one of the nursing staff not only carried organisms of the 80/81 strain in the nose but had suffered from recurrent boils caused by the same organism, and, since McDonald and Timbury (1957) have suggested that staphylococci from subacute infections are more pathogenic than those from a healthy mucous membrane, this may explain the sudden increase in infections The removal of this nurse from duty was the beginning of the end of this particular epidemic, and in the following six months there was only one breast abscess among the Hospital B patients, and this was due to a different phage-type

In contrast, Hospital C, the older building, which was more difficult to clean adequately, had an outbreak of the second type with contamination of dust and air

In Hospital B, the eradication of staff carriers of the epidemic strain, plus the introduction of new nursery techniques to reduce cross-infection, was effective in controlling the outbreak due to the 80/81 strain and also in reducing the “ residual ” sepsis of Williams' third group

Most infants born in Hospital B were seen by one of us (J A M) at a follow-up clinic, at the age of six to eight weeks, and, while some who had been free of infection in Hospital B had developed pustules or conjunctivitis after discharge, almost all infants appeared to clear up spontaneously by the age of two months, regardless of treatment.

During the ten months of the survey only 1 infant had to be transferred from Hospital B to the children's ward of the general hospital This child progressed from crops of pustules to a massive subcutaneous abscess of the forearm No case of staphylococcal pyopneumothorax was seen from Hospital B, though 9 cases (with 4 deaths) were admitted to the children's ward of the hospital during the period. These cases, which show the danger of staphylococcal complications, closely resemble those described by Beaven and Burry (1955) and Briggs (1957)

Our methods of treatment and control correspond closely with those advocated in the monograph of the

TABLE IV—SKIN-SEPSIS RATES IN HOSPITAL B BEFORE AND AFTER INTRODUCTION OF CONTROL MEASURES

No of	January–April		May–October	
Live births	232		402	
—	No	% live births	No	% live births

Breast milk—The "abscess strain" of staphylococcus was isolated from the breast milk in almost half the cases examined 32 samples of breast milk were also obtained from 16 mothers in Hospital B who showed no sign of infection, but whose infant carried or was infected with staphylococci 7 mothers carried the same strain in the milk as that isolated previously from the infant, thus, as in the abscess series, almost half the patients yielded infected milk In 33 cases examined in Hospital B we have not found staphylococci in the breast milk of a woman whose child had a negative nasal swab

Infant Sepsis

In the four months before the introduction of the new nursing techniques in Hospital B, at least 11% (some lesions were not swabbed) of the 232 infants born alive had staphylococcal skin lesions 13 swabs grew staphylococci of phage-type 80/81 In the six months after the application of the new techniques the proportion of infants with staphylococcal skin lesions fell to 6% of 402 live births, organisms of phage-type 80/81 being found in only 3 infants The details of the infant-sepsis rate during the two periods are set out in table IV

Table V analyses the type of lesion and the results of bacteriological examination Only 6 out of 20 "sticky eyes" and 4 out of 12 pustules produced coagulase-positive staphylococci, whereas all cases of paronychia were caused by this organism

The nose and lesion of an infant were swabbed at the same time on 11 occasions, 5 of these pairs grew coagulase-positive staphylococci from both swabs, and in 4 the identical organism was present in both nose and lesion

Umbilical sepsis—No frank examples of umbilical sepsis were encountered during the period of this study 14 umbilical swabs were examined for various reasons and when bacteriological culture was carried out it was found that in only 3 cases were coagulase-positive staphylococci present, while 3 others carried *Escherichia coli* From the remaining 8 swabs either coagulase-negative staphylococci were obtained or there was no growth

Nasal Carriage by Staff

The incidence of coagulase-positive staphylococci in the nose of staff personnel is shown in table VI The variation in numbers of Hospital B staff swabbed is due to the *inclusion of cleaning and domestic staff* in the latter two surveys and to the presence of a new class of trainee nurses in September

While the proportion carrying coagulase-positive staphylococci (positive carriers) varied from 22% to 48%, the proportion of penicillin-resistant staphylococci remained about 70% Similar figures were obtained from the medical staff The single carrier of type 80 81 (among the nursing staff) in September was a "persistent carrier", first identified in January as the probable source *of the 80/81 strain in Hospital B nursery infections*

41 of the Hospital B staff (nursing, cleaning, and domestic) were present for both the *May* and September surveys 20 of these were non-carriers on both occasions 11 who were positive in *May* had become negative by September, while only 2 non-carriers in *May* were positive in September 8 were positive on both occasions, 4 of them carrying the same *or a closely related strain (as shown by phage-typing* and sensitivity pattern) on both occasions

TABLE V—TYPE OF LESION AND BACTERIOLOGICAL RESULTS (IN A SIX-MONTH PERIOD WITH 402 LIVE BIRTHS)

—	Lesion					
	"Sticky eyes"	Skin				Total skin
		Pustules	Blisters	Scabs	Paronychia	
No swabbed	20	12	4	2	7	25
No producing coagulase-positive staphylococci	6	4	3	2	7	16
No producing coagulase-*negative staphylococci*	9	7	1	0	0	8
Other organisms	1	0	0	0	0	0
No growth	4	1	0	0	0	1

One pædiatrician who visited Hospital B weekly had exchanged a penicillin-sensitive strain that was untypable in May, for a highly resistant strain, phage-type *80/81* in September This was almost certainly acquired from the children's ward of the hospital, where *cases of staphylococcal* empyema due to the phage-type 80/81 were under his care

Nasal Carriage by Mothers and Infants

In Hospital B only 2 women of the 113 examined carried the 80/81 strain on admission, and 1 had lost it by the tenth day The overall maternal carriage rate of coagulase-positive staphylococci was 30% to 36%, but in this group the incidence of penicillin-resistant strains was *half* that of the nurses or *infants* The *small* group of 19 mothers in Hospital C gave a similar figure (30%) 41% of the 22 infants in Hospital C were carriers at the time

TABLE VI—NASAL CARRIAGE OF COAGULASE-POSITIVE *STAPHYLOCOCCI*

—	Source of swab		No of swabs	No coagulase-positive	% coagulase-positive	No penicillin resistant	% penicillin resistant	No. of 80 81 strain
Hospital B	Staff (nurses only)	January	36	8	22	5	63	2
	Staff (nursing and cleaning)	May	46	22	48	15	68	4
	Staff (nursing and cleaning)	September	55	16	29	12	76	1
	Staff (medical)	May	8	3	38	2	—	0
	Staff (medical)	*September*	11	4	36	2	—	1
	Mothers (April, May, June)	1st day	113	34	30	16	17	2
		10th day	113	41	36	13	32	1
	Infants (April, May, June)	4th day	113	22	19	13	59	1
		10th day	*113*	39	34	29	74	2
Hospital C	Staff (nursing and cleaning)		21	6	22	4	19	1
	Mothers		19	6	32	4	*21*	0

Hospital C	Dust and air (nurseries, wards, and theatre)		43	9	21	4	9	2

of examination, but since their ages varied from a few hours to fourteen days, this is a lower figure than would have been obtained by swabbing each of these infants in its second week of life.

Dust and Air

No coagulase-positive staphylococci were isolated from the samples taken from the nurseries and theatres in Hospital B, although much dust and a variety of organisms were obtained from various sources. In the older institution (Hospital C), however, 9 of 43 specimens were positive, 2 being identified as type 80/81 (table VI).

Discussion

Since the description in Australia, by Rountree and Freeman (1955), of a newly identified strain of staphylococcus, the phage-type 80 or 80/81, this strain has now been identified in over 40 epidemics in many parts of the world (Shaffer 1957). Since it was first identified in New Zealand as a phage 52A variant (Battersby and Stringer 1954) and subsequently typed (weakly) as 42E/7/73 (Beaven and Burry 1956), Shaffer (1957) has shown the identity of the type 80 or 80/81 with the Canadian strain V-81, and his 42B/47C/44A/52/80/81 strain in the U.S.A. This strain appears to show a predilection for maternity homes (Markham and Shott 1958).

The presence of a particular strain of staphylococci in maternity hospitals is an interesting and as yet unsolved problem. It does appear, however, that the type 80/81 and certain other strains of staphylococcus find the environment of a maternity home particularly well suited to their propagation. It has been suggested by Rountree and Freeman (1955) and Gillespie and Alder (1957) that this strain was of exceptional virulence, but in view of the frequency with which it occurred in minor lesions and the comparative rarity of severe complications, the property of "exceptional" virulence cannot be attributed to the organism seen here.

It is now accepted (Rountree et al. 1956) that breast abscesses during lactation are almost invariably due to staphylococci acquired in the maternity home, often from an infected infant, and our survey confirms these findings. Thus the control of an epidemic of breast abscesses involves the control of neonatal infection in the maternity home. Further, since asymptomatic carriage of staphylococci seems to be almost as dangerous (both for mother and infant) as frank sepsis, nasal carriage of staphylococci by the infants is of importance. It was gratifying to find that the nasal carriage of all coagulase-positive staphylococci by the infants was reduced to under 40% by the measures described. This figure compares most favourably with those quoted by Gairdner (1954) and others.

Duncan and Walker (1942) showed that staphylococci were common in maternal milk, and they found that these organisms were derived from the infant's nose or throat (which was colonised first) and not from the mother's nose. It appeared to us that the importance of breast milk in the transmission of staphylococci had not been fully appreciated, and this view has been confirmed independently by Wysham (1957).

In a maternity home, where dust and aerial contamination is common, a woman with cracked nipples appears to be at a considerable risk regardless of the state of her infant. This may well have been the explanation of 4 of the Hospital C patients, none of whom carried staphylococci in their milk, but who, 2 or 3 at a time, had all been in one four-bed ward. Milk may be much more important as a vector in a unit such as Hospital B where cleaning is effective and dust and aerial contamination in the wards slight or absent. Under such conditions, the train of events in the production of a breast abscess may be introduction by a staff carrier, transfer to infant by hand or aerial spread, transfer from infant to infant in the nursery by hand or air, from infant to maternal milk, whence, in the presence of engorgement (of all or a part of the breast) or cracked nipples, an abscess develops.

The technique of antenatal expression of colostrum advocated by Waller (1946) is recommended to all women attending the antenatal clinic of Hospital B, and only 3 out of 24 patients with breast abscesses had practised this exercise. The benefits of this expression may not only be easier and more effective lactation but also, through improved function of the duct system of the breast, at least some degree of protection against abscess formation. The periodical examination of samples of bulk breast milk from a maternity home may be a valuable screening procedure, since, if a sample produces coagulase-positive staphylococci, a search may be made for the woman responsible. It has also been valuable to culture the milk of the patient in any case of pyrexia of unknown origin in the puerperium.

Williams (1956) described three types of neonatal sepsis: staphylococcal infections of one phage-type from a single source (such as a nurse with boils), infections due to staphylococci which are of one type but are widespread in the environment, and infections by several phage-types which are similar to those carried by the nurses. This last group he considers, is due to inadequate techniques. It seems that these are not mutually exclusive and that the first, if not rapidly controlled, would lead to the second. The experience in Hospital B corresponds closely to Williams' first group, since the sudden appearance of an epidemic of breast abscesses suggested that a new organism especially well adapted for survival in a maternity hospital had been introduced. When this possibility was examined in Hospital B, it was found that one of the nursing staff not only carried organisms of the 80/81 strain in the nose but had suffered from recurrent boils caused by the same organism, and, since McDonald and Timbury (1957) have suggested that staphylococci from subacute infections are more pathogenic than those from a healthy mucous membrane, this may explain the sudden increase in infections. The removal of this nurse from duty was the beginning of the end of this particular epidemic, and in the following six months there was only one breast abscess among the Hospital B patients, and this was due to a different phage-type.

In contrast, Hospital C, the older building, which was more difficult to clean adequately, had an outbreak of the second type with contamination of dust and air.

In Hospital B, the eradication of staff carriers of the epidemic strain, plus the introduction of new nursery techniques to reduce cross-infection, was effective in controlling the outbreak due to the 80/81 strain and also in reducing the "residual" sepsis of Williams' third group.

Most infants born in Hospital B were seen by one of us (J. A. M.) at a follow-up clinic, at the age of six to eight weeks, and, while some who had been free of infection in Hospital B had developed pustules or conjunctivitis after discharge, almost all infants appeared to clear up spontaneously by the age of two months, regardless of treatment.

During the ten months of the survey only 1 infant had to be transferred from Hospital B to the children's ward of the general hospital. This child progressed from crops of pustules to a massive subcutaneous abscess of the forearm. No case of staphylococcal pyopneumothorax was seen from Hospital B, though 9 cases (with 4 deaths) were admitted to the children's ward of the hospital during the period. These cases, which show the danger of staphylococcal complications, closely resemble those described by Beaven and Burry (1955) and Briggs (1957).

Our methods of treatment and control correspond closely with those advocated in the monograph of the

TABLE IV—SKIN-SEPSIS RATES IN HOSPITAL B BEFORE AND AFTER INTRODUCTION OF CONTROL MEASURES

No of	January–April		May–October	
Live births	232		402	
—	No	% live births	No	% live births
Skin lesions swabbed	26	11	25	6
Coagulase-positive swabs	23	10	15	3.5
80/81 strain	13	6	3	0.7

Breast milk—The "abscess strain" of staphylococcus was isolated from the breast milk in almost half the cases examined 32 samples of breast milk were also obtained from 16 mothers in Hospital B who showed no sign of infection, but whose infant carried or was infected with staphylococci 7 mothers carried the same strain in the milk as that isolated previously from the infant, thus, as in the abscess series, almost half the patients yielded infected milk In 33 cases examined in Hospital B we have not found staphylococci in the breast milk of a woman whose child had a negative nasal swab

Infant Sepsis

In the four months before the introduction of the new nursing techniques in Hospital B, at least 11% (some lesions were not swabbed) of the 232 infants born alive had staphylococcal skin lesions 13 swabs grew staphylococci of phage-type 80/81 In the six months after the application of the new techniques the proportion of infants with staphylococcal skin lesions fell to 6% of 402 live births, organisms of phage-type 80/81 being found in only 3 infants The details of the infant-sepsis rate during the two periods are set out in table IV

Table V analyses the type of lesion and the results of bacteriological examination Only 6 out of 20 "sticky eyes" and 4 out of 12 pustules produced coagulase-positive staphylococci, whereas all cases of paronychia were caused by this organism

The nose and lesion of an infant were swabbed at the same time on 11 occasions, 5 of these pairs grew coagulase-positive staphylococci from both swabs, and in 4 the identical organism was present in both nose and lesion

Umbilical sepsis—No frank examples of umbilical sepsis were encountered during the period of this study 14 umbilical swabs were examined for various reasons and when bacteriological culture was carried out it was found that in only 3 cases were coagulase-positive staphylococci present, while 3 others carried *Escherichia coli* From the remaining 8 swabs either coagulase-negative staphylococci were obtained or there was no growth

Nasal Carriage by Staff

The incidence of coagulase-positive staphylococci in the nose of staff personnel is shown in table VI The variation in numbers of Hospital B staff swabbed is due to the inclusion of cleaning and domestic staff in the latter two surveys and to the presence of a new class of trainee nurses in September

While the proportion carrying coagulase-positive staphylococci (positive carriers) varied from 22% to 48%, the proportion of penicillin-resistant staphylococci remained about 70% Similar figures were obtained from the medical staff The single carrier of type 80/81 (among the nursing staff) in September was a "persistent carrier", first identified in January as the probable source of the 80/81 strain in Hospital B nursery infections

41 of the Hospital B staff (nursing, cleaning, and domestic) were present for both the May and September surveys 20 of these were non-carriers on both occasions 11 who were positive in May had become negative by September, while only 2 non-carriers in May were positive in September 8 were positive on both occasions, 4 of them carrying the same or a closely related strain (as shown by phage-typing and sensitivity pattern) on both occasions

TABLE V—TYPE OF LESION AND BACTERIOLOGICAL RESULTS (IN A SIX-MONTH PERIOD WITH 402 LIVE BIRTHS)

—	Lesion					
	"Sticky eyes"	Skin				Total skin
		Pustules	Blisters	Scabs	Paronychia	
No swabbed	20	12	4	2	7	25
No producing coagulase-positive staphylococci	6	4	3	2	7	16
No producing coagulase-negative staphylococci	9	7	1	0	0	8
Other organisms	1	0	0	0	0	0
No growth	4	1	0	0	0	1

One pædiatrician who visited Hospital B weekly had exchanged a penicillin-sensitive strain that was untypable in May, for a highly resistant strain, phage-type 80/81 in September This was almost certainly acquired from the children's ward of the hospital, where cases of staphylococcal empyema due to the phage-type 80/81 were under his care

Nasal Carriage by Mothers and Infants

In Hospital B only 2 women of the 113 examined carried the 80/81 strain on admission, and 1 had lost it by the tenth day The overall maternal carriage rate of coagulase-positive staphylococci was 30% to 36%, but in this group the incidence of penicillin-resistant strains was half that of the nurses or infants The small group of 19 mothers in Hospital C gave a similar figure (30%) 41% of the 22 infants in Hospital C were carriers at the time

TABLE VI—NASAL CARRIAGE OF COAGULASE-POSITIVE STAPHYLOCOCCI

—	Source of swab		No of swabs	No coagulase-positive	% coagulase-positive	No penicillin resistant	% penicillin resistant	No of 80/81 strain

Australian National Health and *Medical Research Council* (Rountree et al 1956) (which contains an extensive bibliography), two points from which have been adopted here the use of 2% gentian violet in 70% alcohol for local application to pustules and the discontinuance of routine eye-drops at birth

It seems that there must be a minimum level of sepsis of the third type, since it is not practicable, nor are we convinced of the advisability of treating all nasal carriers of coagulase-positive staphylococci, as it has been suggested (Rountree and Barbour 1951) that carriage of one strain (possibly penicillin-sensitive) may protect against the acquisition of a more virulent or more resistant strain, and it became apparent, with the decrease in amount of sepsis in Hospital B after the adoption of the new techniques, that without treatment 27% of the staff present in both May and September ceased to carry coagulase-positive strains This exceeds the "spontaneous reversion-rate" among transient carriers which has been variously assessed between 1% (Gould 1955) and 15% (Rountree and Barbour 1951) Persistence of nasal carriage has been assessed at *15%–30% for different groups, and our figure of 19% is* similar to that of Hutchison et al (1957) and others *Half* of these nurses persisted in carrying a given strain 48% of the 41 nurses were negative on both occasions, but their progress was not followed in detail during the intervening months

The importance of umbilical carriage has been emphasised by Jellard (1957), who showed that 70% of infants had contaminated cords by the fourth day of life This figure was halved by the regular application of triple dye to the cord Our small series of umbilical swabs (only 3 out of 14 were positive) seems to correspond to Jellard's treated group and we feel that, provided adequate care is given to the umbilicus, it need not become an important source of organisms

It thus seems probable that the epidemic in Hospital A began with the nurse who had crops of boils In the nursery, once infection was introduced, the presence of staphylococci was perpetuated by transfer from cot to cot by hand or aerial transfer, thence to the mother's breast via the milk In Hospital C, however, dust may have played a more important part in cross-infection between women in the same ward

This sequence provides a basis for methods of control, which are thus designed to prevent the introduction of fresh infection by the epidemic strain, and to eradicate the nursery "reservoir" of infection, by prevention of transfer from staff to infant and from infant to infant.

Summary

A further outbreak of staphylococcal infection in two maternity units produced 27 maternal breast abscesses The staphylococcal strain responsible was the phage-type 80/81

The infant was found to be a frequent source of maternal infection and was usually contaminated either directly, or by aerial transmission, from staff carriers The transfer of staphylococci from the infant to the maternal breast milk is important in the pathogenesis of breast abscess

Neonatal sepsis rates were assessed before and after the introduction of control measures Maternal and infant nasal carrier-rates over a three months' period (in the absence of severe sepsis) were investigated The staff carrier-rates were assessed on three occasions in ten months

It is concluded that a nursery may be "seeded" with staphylococci from a nasal carrier among the staff, and that a nursery "reservoir" of staphylococci may persist by hand or air transfer from infant to infant An infant carrying staphylococci may transmit the organism to the mother's breast, either directly via a cracked nipple, or by inoculation of the breast milk, and a breast abscess may then develop

This work was done during the tenure by one of us (J A M) of the Lady King scholarship and was supported by a grant from that fund Our thanks are due to Prof J L Wright, Prof J A R Miles, Dr M McGeorge, Mr H Shott, and to the matrons and staffs of the hospitals, for their advice and cooperation

ACUTE LEUKÆMIA IN AN INFANT FOLLOWING EXCESSIVE INTRAUTERINE IRRADIATION

F W Gunz

HÆMATOLOGIST

R A Borthwick
M Sc N Z
SENIOR PHYSICIST

G L Rolleston
M B N Z, D M R D, F C R A
DIRECTOR OF RADIOLOGY

CHRISTCHURCH HOSPITAL, CHRISTCHURCH, NEW ZEALAND

LEUKÆMIA seldom occurs below the age of one, and is then peculiarly intractable In reporting such a case here, our main purpose is to discuss its ætiology After the infant's death the suspicion arose that its mother might have been given an unusually heavy dose of diagnostic X rays during pregnancy, and that this had something to do with the leukæmia (Stewart et al 1956) Calculations and experiment confirmed that the child must have received a large quantity of X rays during the latter part of intrauterine life They also showed how this quantity could have been much reduced

Case-report

At the age of 10 months the baby was sent to our hospital with a pustular rash For about six weeks she had bruised readily and for two weeks she had been very pale

She was a fourth child, and, though the three siblings were normal, there had been some toxæmia in each pregnancy, all the fœtuses being very large The mother was very obese (238 lb), and in this fourth pregnancy, because of doubt about the position of the fœtus, three X-ray examinations were undertaken, with a total of five exposures of which three were anteroposterior, and two were lateral projections The fœtus initially lay as a breech and then transversely After an external version, surgical induction was performed at an estimated date of 37 weeks Labour was quick and uncomplicated, and the infant was apparently normal, weighing *9 lb 12 oz* She developed much as her siblings had done, and was bright and cheerful, though always a rather capricious feeder She sat up at 7 months, and at 10 months had two teeth

FŒTAL EXPOSURES

Date	View	Kv	mAs	Focal skin distance	Skin dose	Central fœtus depth	Dose to centre of fœtus
Nov. 15	A.P.	78	550	19 in.	53·2r	4·0 in.	6·15r

„ 28	A.P.	76	500	19 in.	46·0r	4·0 in.	5·3r
Dec. 7	A.P.	76	500	19 in.	46·0r	4·5 in.	4·1r
„ 7	Lat. L. to R.	76	500	22 in.	34·2r	6·0 in.	1·4r
Total							25·35r

Dose to centre of fœtal skull 57·3r.
Dose to mean centre of fœtal tibiæ 23·6r.
Integral dose to whole fœtal body app. 0·1 mega-gram-röntgen.
A.P. = anteroposterior. Lat. = lateral. L. to R. = left to right.

When she was admitted, the lymph-nodes on both sides of the neck were slightly enlarged, the spleen could be felt 2 in., and the liver 1½ in. below the costal margin. The blood contained only 3·5 g. hæmoglobin per 100 ml., and the white-cell count was 41,000 per c.mm. rising to 70,000 (1400 neutrophil polymorphs, 14,700 lymphocytes, 700 monocytes, 5600 myelocytes, and 47,600 blast cells with very primitive nuclei and huge nucleoli), platelets 36,000 per c.mm. The findings resembled those of the "myelomonocytic (Naegeli)" type of acute granulocytic leukæmia usually seen in much older patients.

The baby was transfused and given prednisone 20 mg. daily, without improvement. She developed a staphylococcal septicæmia and died on the 11th hospital day. Postmortem examination confirmed the diagnosis of acute granulocytic leukæmia and staphylococcal pyæmia.

The Radiation Exposures

The mother had been radiographed for fœtal presentation on Nov. 15, Nov. 28, and Dec. 7 (the day before delivery). Because of her obesity, the exposure factors were much greater than is usual. For the anteroposterior examinations she was supine, and for both laterals she lay on her right side. No added filter was used for any of the exposures.

The table shows the focal distances and the location of the various parts of the fœtus, as estimated from an analysis of the films, making allowance for radiographic magnification and the sag of the fœtal region during the lateral exposures. There must necessarily be some inaccuracy in such estimates, but we believe that these are approximately correct. It is worth noting that had the *first lateral* exposure (Nov. 15) been given with the patient lying on her left side instead of the right it would have contributed only 1·4r instead of 8·4r.

The röntgen exposure doses were measured with a calibrated Victoreen r-meter. An average back scatter factor of 1·26 was found experimentally with a pressed wood phantom and a flat plate ionisation chamber. The chamber was also used to determine the percentage depth dose in pressed wood, and the values obtained were used in calculating the röntgen exposure received at the centre of the fœtus.

In this analysis we have chosen to estimate the radiation exposure to the centre of the fœtal skeleton. There appear to be three main methods of stating the radiation exposure for correlation with leukæmia—namely (*a*) the average dose to the fœtus (Bewley et al. 1957), (*b*) the integral dose to the whole body (Wheatley and Geilinger 1957) and (*c*) the dose to the centre of the fœtal skeleton (Clayton et al. 1957). Any assessment of the average dose to the fœtus is difficult, and so is the application to the fœtal body of the method for estimating the integral dose. The calculation of the dose to the centre of the fœtal skeleton is simpler and more accurate. However, we have attempted a very rough estimate of the integral dose, and we include it to indicate the order of its magnitude. We also add estimates of the dose received by other parts of the fœtal skeleton.

Discussion

In older children leukæmia is almost exclusively lymphocytic, but in the very young it is commonly granulocytic. In the very rare cases of congenital leukæmia, too, there is a great predominance of granulocytic forms—e.g., 28 granulocytic to 4 lymphocytic (Reimann et al. 1955). It appears permissible to group together congenital leukæmias and those occurring up to the age of perhaps one year, since they tend to show similar and distinctive clinical features (especially a hyperacute course) and hæmatological findings. The question arises whether their ætiology may be equally distinctive.

In 1956 Stewart et al. published a preliminary report which showed that in a group of children dying from leukæmia and other malignant diseases diagnostic irradiation of the mother's abdomen during pregnancy had been significantly more frequent than in a control group. These findings suggested that leukæmia in children could sometimes be caused by diagnostic irradiation of the maternal pelvis during pregnancy. In criticism of this conclusion (Rabinowitch 1956, 1957, Reid 1957, Jackson 1958, Parlee 1958) the most important argument has been that the dose of X rays received by the fœtus during such exposures must have been far too small to cause leukæmia. Thus the average dose of 1–2·5r (Rabinowitch) is insignificant when compared with the doses administered to patients with ankylosing spondylitis (Court-Brown and Doll 1957) or to those inhabitants of Hiroshima and Nagasaki who later developed leukæmia. Authors who have been inclined to accept the leukæmogenic action of diagnostic irradiation in pregnancy have concluded that "a dose of 2500mr doubles the leukæmia rate" (Hodges 1958).

Our case shows that, whatever the *average* dose given to pregnant women and their fœtuses, it is possible, using standard techniques and only those exposures which are regarded as essential for the safe conduct of a difficult obstetrical case, to administer very much higher doses than have yet been mentioned in the discussion of Stewart's figures. Indeed, the quantity of radiation received by the fœtus in our case (a mean of about 25r) was about the same as that probably received by the majority of those inhabitants of Hiroshima and Nagasaki who survived the atomic bombing at distances of 1500–2000 metres from the hypocentre (mean 50 rem)—a dose great enough to raise the leukæmia incidence among them by 200–300% compared with people in the "control" zone at more than 2000 metres from the hypocentre (Lewis 1957). Hence, to account for leukæmia in cases resembling ours, it is unnecessary to invoke the possibly very high sensitivity of the fœtal hæmopoietic system to the effects of ionising radiation. Again, accepting with reservations the estimates of the integral body dose, that received by irradiated spondylitics is (allowing for the difference in body-weight) in most cases only six to twenty times as large as that received by our fœtus, and not several hundred times, as deduced by Rabinowitch.

If irradiation caused the leukæmia in our patient, the latent period between irradiation and the onset of the leukæmia was much shorter than that in Japan, which was upwards of 3 years (Moloney and Lange 1954a), or in the British series of irradiated spondylitics (2–5 years, Court-Brown and Doll 1957). But since we were dealing with a very young infant, this short latency does not rule out a causal relationship. It may be significant that the leukæmia was granulocytic, for, except in Simpson et al. (1956) cases of lymphocytic leukæmia following irradiation of the thymus in childhood, nearly all reported post-irradiation leukæmias have been granulocytic—either acute or chronic (Court-Brown and Doll 1957, Moloney and Lange 1954b). It seems advisable to analyse future cases of granulocytic leukæmia in infancy ("congenital" and "acquired") with particular care

Australian National Health and Medical Research Council (Rountree et al 1956) (*which contains an extensive bibliography*), two points from which have been adopted here the use of 2% gentian violet in 70% alcohol for local application to pustules and the discontinuance of routine eye-drops at birth

It seems that there must be a minimum level of sepsis of the third type, since it is not practicable, nor are we convinced of the advisability of treating all nasal carriers of coagulase-positive staphylococci, as it has been suggested (Rountree and Barbour 1951) that carriage of one strain (possibly penicillin-sensitive) may protect against the acquisition of a more virulent or more resistant strain, and it became apparent, with the decrease in amount of sepsis in Hospital B after the adoption of the new techniques, that without treatment 27% of the staff present in both May and September ceased to carry coagulase-positive strains This exceeds the "spontaneous reversion-rate" among transient carriers which has been variously assessed between 1% (Gould 1955) and 15% (Rountree and Barbour 1951) Persistence of nasal carriage has been assessed at 15%–30% for different groups, and our figure of 19% is similar to that of Hutchison et al (1957) and others Half of these nurses persisted in carrying a given strain 48% of the 41 nurses were negative on both occasions, but their progress was not followed in detail during the intervening months

The importance of umbilical carriage has been emphasised by Jellard (1957), who showed that 70% of infants had contaminated cords by the fourth day of life This figure was halved by the regular application of triple dye to the cord Our small series of umbilical swabs (only 3 out of 14 were positive) seems to correspond to Jellard's treated group and we feel that, provided adequate care is given to the umbilicus, it need not become an important source of organisms

It thus seems probable that the epidemic in Hospital A began with the nurse who had crops of boils In the nursery, once infection was introduced, the presence of staphylococci was perpetuated by transfer from cot to cot by hand or aerial transfer, thence to the mother's breast via the milk In Hospital C, however, dust may have played a more important part in cross-infection between women in the same ward

This sequence provides a basis for methods of control, which are thus designed to prevent the introduction of fresh infection by the epidemic strain, and to eradicate the nursery "reservoir" of infection, by prevention of transfer from staff to infant and from infant to infant

Summary

A further outbreak of staphylococcal infection in two maternity units produced 27 maternal breast abscesses The staphylococcal strain responsible was the phage-type 80/81

The infant was found to be a frequent source of maternal infection and was usually contaminated either directly, or by aerial transmission, from staff carriers The transfer of staphylococci from the infant to the maternal breast milk is important in the pathogenesis of breast abscess

Neonatal sepsis rates were assessed before and after the introduction of control measures Maternal and infant nasal carrier-rates over a three months' period (in the absence of severe sepsis) were investigated The staff carrier-rates were assessed on three occasions in ten months

It is concluded that a nursery may be "seeded" with staphylococci from a nasal carrier among the staff, and that a nursery "reservoir" of staphylococci may persist by hand or air transfer from infant to infant An infant carrying staphylococci may transmit the organism to the mother's breast, either directly via a cracked nipple, or by inoculation of the breast milk, and a breast abscess may then develop

This work was done during the tenure by one of us (J A M) of the Lady King scholarship and was supported by a grant from that fund Our thanks are due to Prof J L Wright, Prof J A R Miles, Dr M McGeorge, Mr H Shott, and to the matrons and staffs of the hospitals, for their advice and cooperation

CHRISTCHURCH HOSPITAL, CHRISTCHURCH, NEW ZEALAND

Leukæmia seldom occurs below the age of one, and is then peculiarly intractable In reporting such a case here, our main purpose is to discuss its ætiology After the infant's death the suspicion arose that its mother might have been given an unusually heavy dose of diagnostic X rays during pregnancy, and that this had something to do with the leukæmia (Stewart et al 1956) Calculations and experiment confirmed that the child must have received a large quantity of X rays during the latter part of intrauterine life They also showed how this quantity could have been much reduced

Case-report

At the age of 10 months the baby was sent to our hospital with a pustular rash For about six weeks she had bruised readily and for two weeks she had been very pale

She was a fourth child, and, though the three siblings were normal, there had been some toxæmia in each pregnancy, all the fœtuses being very large The mother was very obese (238 lb), and in this fourth pregnancy, because of doubt about the position of the fœtus, three X-ray examinations were undertaken, with a total of five exposures of which three were anteroposterior, and two were lateral projections The fœtus initially lay as a breech and then transversely After an external version, surgical induction was performed at an estimated date of 37 weeks Labour was quick and uncomplicated, and the infant was apparently normal, weighing 9 lb 12 oz She developed much as her siblings had done, and was bright and cheerful, though always a rather capricious feeder She sat up at 7 months, and at 10 months had two teeth

Integral dose to whole fœtal body app. 0·1 mega-gram-röntgen.
A.P = anteroposterior. Lat. = lateral. L. to R. = left to right.

When she was admitted, the lymph-nodes on both sides of the neck were slightly enlarged, the spleen could be felt 2 in., and the liver 1½ in. below the costal margin. The blood contained only 3·5 g. hæmoglobin per 100 ml., and the white-cell count was 41,000 per c.mm. rising to 70,000 (1400 neutrophil polymorphs, 14,700 lymphocytes, 700 monocytes, 5600 myelocytes, and 47,600 blast cells with very primitive nuclei and huge nucleoli), platelets 36,000 per c.mm. The findings resembled those of the "myelomonocytic (Naegeli)" type of acute granulocytic leukæmia usually seen in much older patients.

The baby was transfused and given prednisone 20 mg. daily, without improvement. She developed a staphylococcal septicæmia and died on the 11th hospital day. Postmortem examination confirmed the diagnosis of acute granulocytic leukæmia and staphylococcal pyæmia.

The Radiation Exposures

The mother had been radiographed for fœtal presentation on Nov. 15, Nov. 28, and Dec. 7 (the day before delivery). Because of her obesity, the exposure factors were much greater than is usual. For the anteroposterior examinations she was supine, and for both laterals she lay on her right side. No added filter was used for any of the exposures.

The table shows the focal distances and the location of the various parts of the fœtus, as estimated from an analysis of the films, making allowance for radiographic magnification and the sag of the fœtal region during the lateral exposures. There must necessarily be some inaccuracy in such estimates, but we believe that these are approximately correct. It is worth noting that had the first lateral exposure (Nov. 15) been given with the patient lying on her left side instead of the right it would have contributed only 1·4r instead of 8·4r.

The röntgen exposure doses were measured with a calibrated Victoreen r-meter. An average back scatter factor of 1·26 was found experimentally with a pressed wood phantom and a flat plate ionisation chamber. The chamber was also used to determine the percentage depth dose in pressed wood, and the values obtained were used in calculating the röntgen exposure received at the centre of the fœtus.

In this analysis we have chosen to estimate the radiation exposure to the centre of the fœtal skeleton. There appear to be three main methods of stating the radiation exposure for correlation with leukæmia—namely (*a*) the average dose to the fœtus (Bewley et al. 1957), (*b*) the integral dose to the whole body (Wheatley and Geilinger 1957) and (*c*) the dose to the centre of the fœtal skeleton (Clayton et al. 1957). Any assessment of the average dose to the fœtus is difficult, and so is the application to the fœtal body of the method for estimating the integral dose. The calculation of the dose to the centre of the fœtal skeleton is simpler and more accurate. However, we have attempted a very rough estimate of the integral dose, and we include it to indicate the order of its magnitude. We also add estimates of the dose received by other parts of the fœtal skeleton.

Discussion

In older children leukæmia is almost exclusively lymphocytic, but in the very young it is commonly granulocytic. In the very rare cases of congenital leukæmia, too, there is a great predominance of granulocytic forms—e.g., 28 granulocytic to 4 lymphocytic (Reimann et al. 1955). It appears permissible to group together congenital leukæmias and those occurring up to the age of perhaps one year, since they tend to show similar and distinctive clinical features (especially a hyperacute course) and hæmatological findings. The question arises whether their ætiology may be equally distinctive.

In 1956 Stewart et al. published a preliminary report which showed that in a group of children dying from leukæmia and other malignant diseases diagnostic irradiation of the mother's abdomen during pregnancy had been significantly more frequent than in a control group. These findings suggested that leukæmia in children could sometimes be caused by diagnostic irradiation of the maternal pelvis during pregnancy. In criticism of this conclusion (Rabinowitch 1956, 1957, Reid 1957, Jackson 1958, Parlee 1958) the most important argument has been that the dose of X rays received by the fœtus during such exposures must have been far too small to cause leukæmia. Thus the average dose of 1–2·5r (Rabinowitch) is insignificant when compared with the doses administered to patients with ankylosing spondylitis (Court-Brown and Doll 1957) or to those inhabitants of Hiroshima and Nagasaki who later developed leukæmia. Authors who have been inclined to accept the leukæmogenic action of diagnostic irradiation in pregnancy have concluded that "a dose of 2500mr doubles the leukæmia rate" (Hodges 1958).

Our case shows that, whatever the *average* dose given to pregnant women and their fœtuses, it is possible, using standard techniques and only those exposures which are regarded as essential for the safe conduct of a difficult obstetrical case, to administer very much higher doses than have yet been mentioned in the discussion of Stewart's figures. Indeed, the quantity of radiation received by the fœtus in our case (a mean of about 25r) was about the same as that probably received by the majority of those inhabitants of Hiroshima and Nagasaki who survived the atomic bombing at distances of 1500–2000 metres from the hypocentre (mean 50 rem)—a dose great enough to raise the leukæmia incidence among them by 200–300% compared with people in the "control" zone at more than 2000 metres from the hypocentre (Lewis 1957). Hence, to account for leukæmia in cases resembling ours, it is unnecessary to invoke the possibly very high sensitivity of the fœtal hæmopoietic system to the effects of ionising radiation. Again, accepting with reservations the estimates of the integral body dose, that received by irradiated spondylitics is (allowing for the difference in body-weight) in most cases only six to twenty times as large as that received by our fœtus, and not several hundred times, as deduced by Rabinowitch.

If irradiation caused the leukæmia in our patient, the latent period between irradiation and the onset of the leukæmia was much shorter than that in Japan, which was upwards of 3 years (Moloney and Lange 1954a), or in the British series of irradiated spondylitics (2–5 years, Court-Brown and Doll 1957). But since we were dealing with a very young infant, this short latency does not rule out a causal relationship. It may be significant that the leukæmia was granulocytic, for, except in Simpson et al. (1956) cases of lymphocytic leukæmia following irradiation of the thymus in childhood, nearly all reported post-irradiation leukæmias have been granulocytic—either acute or chronic (Court-Brown and Doll 1957, Moloney and Lange 1954b). It seems advisable to analyse future cases of granulocytic leukæmia in infancy ("congenital" and "acquired") with particular care

Australian National Health and Medical Research Council (Rountree et al 1956) (which contains an extensive bibliography), two points from which have been adopted here the use of 2% gentian violet in 70% alcohol for local application to pustules and the discontinuance of routine eye-drops at birth

It seems that there must be a minimum level of sepsis of the third type, since it is not practicable, nor are we convinced of the advisability of treating all nasal carriers of coagulase-positive staphylococci, as it has been suggested (Rountree and Barbour 1951) that carriage of one strain (possibly penicillin-sensitive) may protect against the acquisition of a more virulent or more resistant strain, and it became apparent, with the decrease in amount of sepsis in Hospital B after the adoption of the new techniques, that without treatment 27% of the staff present in both May and September ceased to carry coagulase-positive strains This exceeds the "spontaneous reversion-rate" among transient carriers which has been variously assessed between 1% (Gould 1955) and 15% (Rountree and Barbour 1951) Persistence of nasal carriage has been assessed at 15%–30% for different groups, and our figure of 19% is similar to that of Hutchison et al (1957) and others Half of these nurses persisted in carrying a given strain 48% of the 41 nurses were negative on both occasions, but their progress was not followed in detail during the intervening months

The chamber was also used to determine the percentage depth dose in pressed wood, and the values obtained were used in calculating the röntgen exposure received at the centre of the fœtus.

In this analysis we have chosen to estimate the radiation exposure to the centre of the fœtal skeleton. There appear to be three main methods of stating the radiation exposure for correlation with leukæmia—namely (*a*) the average dose to the fœtus (Bewley et al. 1957), (*b*) the integral dose to the whole body (Wheatley and Geilinger 1957) and (*c*) the dose to the centre of the fœtal skeleton (Clayton et al. 1957). Any assessment of the average dose to the fœtus is difficult, and so is the application to the fœtal body of the method for estimating the integral dose. The calculation of the dose to the centre of the fœtal skeleton is simpler and more accurate. However, we have attempted a very rough estimate of the integral dose, and we include it to indicate the order of its magnitude. We also add estimates of the dose received by other parts of the fœtal skeleton.

Discussion

In older children leukæmia is almost exclusively lymphocytic, but in the very young it is commonly granulocytic. In the very rare cases of congenital leukæmia, too, there is a great predominance of granulocytic forms—e.g., 28 granulocytic to 4 lymphocytic (Reimann et al. 1955). It appears permissible to group together congenital leukæmias and those occurring up to the age of perhaps one year, since they tend to show similar and distinctive clinical features (especially a hyperacute course) and hæmatological findings. The question arises whether their ætiology may be equally distinctive.

In 1956 Stewart et al. published a preliminary report which showed that in a group of children dying from leukæmia and other malignant diseases diagnostic irradiation of the mother's abdomen during pregnancy had been significantly more frequent than in a control group. These findings suggested that leukæmia in children could sometimes be caused by diagnostic irradiation of the maternal pelvis during pregnancy. In criticism of this conclusion (Rabinowitch 1956, 1957, Reid 1957, Jackson 1958, Parlee 1958) the most important argument has been that the dose of X rays received by the fœtus during such exposures must have been far too small to cause leukæmia. Thus the average dose of 1–2·5r (Rabinowitch) is insignificant when compared with the doses administered to patients with ankylosing spondylitis (Court-Brown and Doll 1957) or to those inhabitants of Hiroshima and Nagasaki who later developed leukæmia. Authors who have been inclined to accept the leukæmogenic action of diagnostic irradiation in pregnancy have concluded that "a dose of 2500mr doubles the leukæmia rate" (Hodges 1958).

Our case shows that, whatever the *average* dose given to pregnant women and their fœtuses, it is possible, using standard techniques and only those exposures which are regarded as essential for the safe conduct of a difficult obstetrical case, to administer very much higher doses than have yet been mentioned in the discussion of Stewart's figures. Indeed, the quantity of radiation received by the fœtus in our case (a mean of about 25r) was about the same as that probably received by the majority of those inhabitants of Hiroshima and Nagasaki who survived the atomic bombing at distances of 1500–2000 metres from the hypocentre (mean 50 rem)—a dose great enough to raise the leukæmia incidence among them by 200–300% compared with people in the "control" zone at more than 2000 metres from the hypocentre (Lewis 1957). Hence, to account for leukæmia in cases resembling ours, it is unnecessary to invoke the possibly very high sensitivity of the fœtal hæmopoietic system to the effects of ionising radiation. Again, accepting with reservations the estimates of the integral body dose, that received by irradiated spondylitics is (allowing for the difference in body-weight) in most cases only six to twenty times as large as that received by our fœtus, and not several hundred times, as deduced by Rabinowitch.

If irradiation caused the leukæmia in our patient, the latent period between irradiation and the onset of the leukæmia was much shorter than that in Japan, which was upwards of 3 years (Moloney and Lange 1954a), or in the British series of irradiated spondylitics (2–5 years, Court-Brown and Doll 1957). But since we were dealing with a very young infant, this short latency does not rule out a causal relationship. It may be significant that the leukæmia was granulocytic, for, except in Simpson et al. (1956) cases of lymphocytic leukæmia following irradiation of the thymus in childhood, nearly all reported post-irradiation leukæmias have been granulocytic—either acute or chronic (Court-Brown and Doll 1957, Moloney and Lange 1954b). It seems advisable to analyse future cases of granulocytic leukæmia in infancy ("congenital" and "acquired") with particular care

Australian National Health and Medical Research Council (Rountree et al 1956) (which contains an extensive bibliography), two points from which have been adopted here the use of 2% gentian violet in 70% alcohol for local application to pustules and the discontinuance of routine eye-drops at birth

It seems that there must be a minimum level of sepsis of the third type, since it is not practicable, nor are we convinced of the advisability of treating all nasal carriers of coagulase-positive staphylococci, as it has been suggested (Rountree and Barbour *1951*) that carriage of one strain (possibly penicillin-sensitive) may protect against the acquisition of a more virulent or more resistant strain, and it became apparent, with the decrease in amount of sepsis in Hospital B after the adoption of the new techniques, that without treatment 27% of the staff present in both May and September ceased to carry coagulase-positive strains This exceeds the "spontaneous reversion-rate" among transient carriers which has been variously assessed between 1% (Gould 1955) and 15% (Rountree and Barbour 1951) Persistence of nasal carriage has been assessed at 15%–30% for different groups, and our figure of 19% is similar to that of Hutchison et al (1957) and others Half of these nurses persisted in carrying a given strain 48% of the 41 nurses were negative on both occasions, but their progress was not followed in detail during the intervening months

The importance of umbilical carriage has been emphasised by Jellard (1957), who showed that 70% of infants had contaminated cords by the fourth day of life This figure was halved by the regular application of triple dye to the cord Our small series of umbilical swabs (only 3 out of 14 were positive) seems to correspond to Jellard's treated group and we feel that, provided adequate care is given to the umbilicus, it need not become an important source of organisms

It thus seems probable that the epidemic in Hospital A began with the nurse who had crops of boils In the nursery, once infection was introduced, the presence of staphylococci was perpetuated by transfer from cot to cot by hand or aerial transfer, thence to the mother's breast via the milk In Hospital C, however, dust may have played a more important part in cross-infection between women in the same ward

This sequence provides a basis for methods of control, which are thus designed to prevent the introduction of fresh infection by the epidemic strain, and to eradicate the nursery "reservoir" of infection, by prevention of transfer from staff to infant and from infant to infant

Summary

A further outbreak of staphylococcal infection in two maternity units produced 27 maternal breast abscesses *The staphylococcal strain responsible was the phage*-type 80/81

The infant was found to be a frequent source of maternal infection and was usually contaminated either directly, or by aerial transmission, from staff carriers The transfer of staphylococci from the infant to the maternal breast milk is important in the pathogenesis of breast abscess

Neonatal sepsis rates were assessed before and after the introduction of control measures Maternal and infant nasal carrier-rates over a three months' period (in the absence of severe sepsis) were investigated The staff carrier-rates were assessed on three occasions in ten months

It is concluded that a nursery may be "seeded" with staphylococci from a nasal carrier among the staff, and that a nursery "reservoir" of staphylococci may persist by hand or air transfer from infant to infant An infant carrying staphylococci may transmit the organism to the mother's breast, either directly via a cracked nipple, or by inoculation of the breast milk, and a breast abscess may then develop

This work was done during the tenure by one of us (J A. M.) of the Lady King scholarship and was supported by a grant from that fund Our thanks are due to Prof J L Wright, Prof J A. R Miles, Dr M McGeorge, Mr H Shott, and to the matrons and staffs of the hospitals, for their advice and cooperation

ACUTE LEUKÆMIA IN AN INFANT FOLLOWING EXCESSIVE INTRAUTERINE IRRADIATION

F W GUNZ
M D Lond, Ph D Cantab, M R C P
HÆMATOLOGIST

R A. BORTHWICK
M Sc N Z
SENIOR PHYSICIST

G L ROLLESTON
M B N Z, D M R D, F C R A
DIRECTOR OF RADIOLOGY

CHRISTCHURCH HOSPITAL, CHRISTCHURCH, NEW ZEALAND

LEUKÆMIA seldom occurs below the age of one, and is then peculiarly intractable In reporting such a case here, our main purpose is to discuss its ætiology After the infant's death the suspicion arose that its mother might have been given an unusually heavy dose of diagnostic X rays during pregnancy, and that this had something to do with the leukæmia (Stewart et al *1956)* Calculations and experiment confirmed that the child must have received a large quantity of X rays during the latter part of intrauterine life They also showed how this quantity *could have been much reduced*

Case-report

At the age of 10 months the baby was sent to our hospital with a pustular rash For about six weeks she had bruised readily and for two weeks she had been very pale

She was a fourth child, and, though the three siblings were normal, there had been some toxæmia in each pregnancy, all the fœtuses being very large The mother was very obese (238 lb), and in this fourth pregnancy, because of doubt about the position of the fœtus, three X-ray examinations were undertaken, with a total of five exposures of which three were anteroposterior, and two were lateral projections The fœtus initially lay as a breech and then transversely After an external version, surgical induction was performed at an estimated date of 37 weeks Labour was quick and uncomplicated, and the infant was apparently normal, weighing 9 lb 12 oz She developed much as her siblings had done, and was bright and cheerful, though always a rather capricious feeder She sat up at 7 months, and at 10 months had two teeth

Fig 2—Lateral and anteroposterior radiographs of skull Twin cannulas introduced.

root diameter of the screw (0 106 in), and the loaded screw, attached to the screwdriver, is passed along the cannula The encased yttrium-90 passes through the drillhole and penetrates the pituitary gland, while the thread of the screw firmly grips the bone Advancement of the source into a central position is easily accomplished by a few turns of the screw which fix it firmly in the required position (fig 3) If the central threaded rod is first unscrewed the screwdriver can be removed without danger of withdrawing the yttrium-loaded screw from the bone (fig 4)

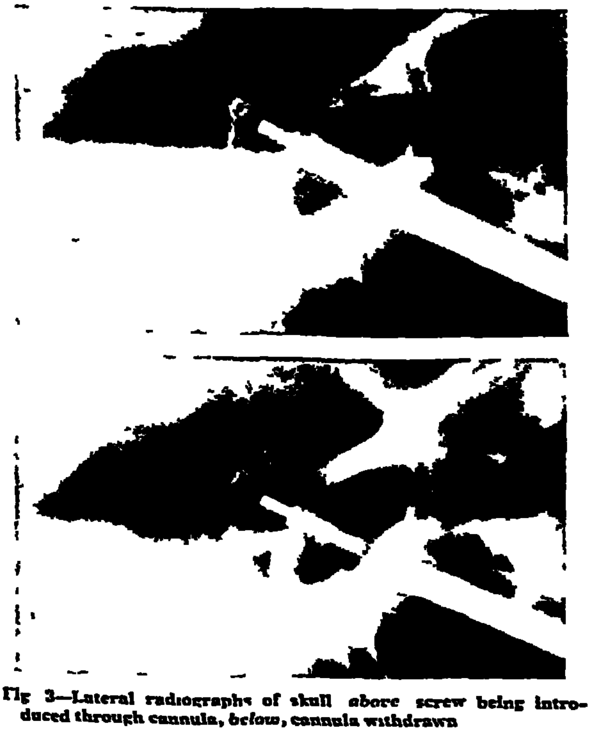

Fig 3—Lateral radiographs of skull *above* screw being introduced through cannula, *below*, cannula withdrawn

Fourteen patients with metastatic mammary cancer, considered unfit for adrenalectomy, have been treated by introducing twin screws each loaded with 5–7 mC yttrium-90 into the pituitary by this method These patients all had advanced disease, and three died from progression of cancer within 8 days of pituitary screw-implantation In all three the gland was entirely destroyed except for a single layer of subcapsular cells That these would probably have failed to survive had the patients lived longer is suggested by the finding of complete destruction of the pituitary in a further patient who died 6 weeks after implantation As in other forms of pituitary ablation, cortisone therapy is required to maintain life after screw-implantation with yttrium-90

We believe that this revised method of radioactive implantation of the pituitary offers distinct advantages over our previous techniques [1 3 4] and ensures that the sources of yttrium-90 are placed with consistent accuracy

We are grateful to Prof C F W Illingworth for allowing us to treat these patients in his unit, and to Mr Angus Macdonald, of the Western Infirmary workshop, and Mr Edward Fahey, of the Regional Physics Department, for technical assistance in constructing the screws and apparatus The postmortem histological examination of the pituitaries was carried out by Dr A T Sandison, of the University Department of Pathology, Western Infirmary

as regards exposure to radiation, and to ascertain whether their history of exposure differs from that of the predominantly lymphocytic group of leukæmias in later childhood Possibly the higher leukæmia incidence found by Stewart et al may be accounted for chiefly by "exceptional" cases like ours

Our patient received during fœtal life a dose of radiation such as has materially increased the leukæmia-rate in an adult population Soon after this infant's mother was examined radiologically, and well before her infant's admission, the technique for obstetrical exposure at our hospital was altered to reduce the amount of radiation received both by mother and fœtus This has been achieved, without any appreciable alteration in the quality of films, by the following means

(1) Additional tube filtration of 2 mm of aluminium
(2) The use of high-speed screens
(3) Doubling the development time of the film
(4) Increasing the anode film distance in erect lateral films of the pelvis from 40 in to 60 in
(5) The use of high kilovoltage techniques

These modifications have resulted in a striking reduction in the X-ray dosage necessary to produce diagnostic films For example if the examinations on our patient, a 17-stone woman, were performed at the present time, the dose to the centre of the fœtus would be approximately 1 9r, or only 8% of that actually received It would be much lower still in the average obstetric case which has been so widely discussed of late

Summary

A 10-month old infant died from acute granulocytic leukæmia

The mother had had three X-ray examinations (five exposures) during late pregnancy Since she was an exceptionally heavy woman, the dose given to her and received by the fœtus was exceptionally large and lay within the range known to be potentially leukæmogenic in adults

Modifications in the technique of radiography which have since been introduced would have diminished the dose received by the fœtus by 92%

The patient reported upon was under the care of Dr J F Landreth, whose permission to publish her record is gratefully acknowledged

Preliminary Communication

SCREW-IMPLANTATION OF THE PITUITARY WITH YTTRIUM-90

COMPLETE necrosis of the pituitary gland can be achieved by implanting two 6 mC rods of yttrium-90 into the sella turcica through twin cannulas inserted transnasally (one through either nostril) under radiological control, and this method of treatment may benefit patients with advanced mammary cancer [1] Consistent and trouble-free destruction of the gland depends primarily on placing the two sources of radiation so that one lies in the centre of each half of the gland A disadvantage of our previous method of implantation was that the rods were sometimes deflected into the space between the gland and the wall of the sella turcica, with the result that irradiation of the gland was incomplete In addition, troublesome rhinorrhœa occurred in ten of the fifty-four patients treated This was believed to be due to radiation necrosis of the diaphragma sellæ caused by faulty placing of the rods

A modified technique has therefore been developed, for use with an image amplifier, to fix the rods in the optimum position In this new method the holes in the anterior wall of the sella, through which the rods have been inserted, are plugged, providing an added protection against leakage of cerebrospinal fluid

A cylindrical rod of yttrium oxide (5 × 2 mm, 68 mg)* is encased in a very thin sharp-pointed nylon sheath in which it is held by a small nylon plug After activation in the Harwell pile, BEPO, this unit is fitted into one end of a stainless steel self-tapping orthopædic screw (Sherman screw size 6, $^5/_{32}$" in diameter)† 0 5 in long This end has been drilled to accommodate the nylon-encased rod and the other end has been turned down and screwed with a 6 BA die (fig 1) This portion of the screw accommodates a similarly threaded but loosely fitting screwdriver When the threaded central rod of the screwdriver is tightened, the screw is firmly clamped, and it can be released only when the rod is loosened

By the use of a director apparatus similar to that previously described,[2] twin 4 mm cannulas are introduced, one through each nostril, until their ends lie against the outer wall of the pituitary fossa opposite the middle of the gland (fig 2) Correct alignment of the cannulas is achieved by screening with the image amplifier A diamond-steel drill is introduced down each cannula to cut a hole in the wall of the fossa equivalent to the

THE LANCET
LONDON 26 JULY 1958

A Memorable Experiment

When **Richard Bright** in 1836 called attention to the association between enlargement of the heart and chronic disease of the kidney, he was in effect asking the first of a series of questions which have taxed the resources of subsequent generations of students For over a hundred years progress, depending as it did on observation, inference, and intuition, was inevitably slow, but it nevertheless became clear that, while high blood-pressure could derive from demonstrable kidney disease, it could also occur in its absence The later recognition that this *essential* hypertension could cause renal damage did nothing to simplify the task of those who were patiently trying to bring order out of chaos The year 1933 witnessed an abrupt increase in both the breadth and the tempo of research, for it was in that year that H F **Goldblatt**, in a historic experiment, showed that in animals simply constricting both renal arteries or one renal artery after excision of the opposite kidney produced a form of sustained hypertension which tallied in most essential respects with the disease in man To mark the 25th anniversary of this experiment the University of Michigan organised a conference on Basic Mechanisms of Arterial Hypertension, at which Dr **Goldblatt** was guest of honour The proceedings of this conference have now been published in a special issue of *Circulation* [1]

The first, and obvious, conclusion that accrued from **Goldblatt**'s work was that the hypertension that arises in the course of structural disease of the kidney may be attributed to impedance of the circulation The next followed quickly on the discovery that in some species, notably the rat,[2] permanent hypertension could be caused by constriction of only one renal artery Such hypertension was found to be followed by the appearance in the opposite kidney of acute arterial necrosis and other lesions characteristic of malignant hypertension which had previously been regarded as inflammatory, and this strengthened the concept of malignant hypertension and simplified the classification of Bright's disease [3] The suggestion that these lesions in the rat are due to spontaneous periarteritis nodosa [4] or pyelonephritis [5] overlooks the fact that they are invariably absent from the " clamped " kidney Likewise the view that hypertension causes arterial necrosis only in the presence of renal excretory failure [5] is not consistent with clinical or experimental facts [6] The work already mentioned also strengthened the clinical suspicion that unilateral renal disease might underlie some cases of hypertension in man, and it is now generally recognised that severe hypertension may occasionally arise in this way and may be dramatically cured, even in the malignant phase, by nephrectomy provided that the primary renal disease is strictly unilateral and that the condition is recognised before significant secondary hypertensive damage has developed in the opposite kidney The detection of this unilateral renal disease is often extremely difficult, for it may take many different forms, from postoperative stenosis of a ureter [7] to pyelonephritis set up by habitual failure to empty the bladder more than once a day [8]

Another early outcome of **Goldblatt**'s experiment was the rediscovery in the normal kidney of the pressor substance renin,[9 10] which had lain buried in the literature for forty years Renin was soon found to be an enzyme [9] producing the polypeptide hypertensin Subsequent developments in chemical technique have made possible first the identification of the inert decapeptide,[11] then the elucidation of the structure of the active octapeptide,[12] and finally the synthesis of this highly active substance which contains as much as 50,000 pressor units per milligramme of nitrogen [13 14] Whether overproduction of renin is responsible for Goldblatt hypertension is still not conclusively proven, but the evidence is very suggestive The strongest evidence relates to the fact that renin is a protein and can be used to prepare a highly specific antibody In animals with renal hypertension passive or active immunity conferred by this antirenin is accompanied by pronounced lowering of the blood-pressure [15] Renin and more recently hypertensin [16] have also been demonstrated in the blood after constriction of the renal artery Hypertension has been maintained for as long as seventeen days in rabbits by continuous intravenous injection of renin,[17] and when such an infusion is discontinued the hypertension persists for about as long as it does when a clip is removed from a renal artery [18]—that is, about four hours A further point relates to the effect of pregnancy During pregnancy in the normal animal the reactivity to renin is lowered,[19] and in rats with Goldblatt hypertension the blood-pressure falls progressively [19 20] It has recently been shown that these two changes are closely related in time [21] The reactivity to hypertensin is not altered in pregnancy [22] The renin hypothesis will not, of course, account for the hypertension which follows total nephrectomy Nor is it clear why the presence of normal kidney tissue tends to mitigate renal hypertension On the other hand, no simple explanation of renoprival hypertension will explain why constricting one renal artery causes hypertension while excising one kidney

Reviews of Books

The First Ten Years of the World Health Organization

Geneva W H O 1958 Pp 538 To be had from H M Stationery Office 20s (paper backed), 25s (cloth)

IT was natural and proper that the World Health Organisation should celebrate the first ten years of its existence with a commemorative volume Apart from its own official reports and proceedings, no account of its work as a whole has been written since Goodman's more general and historical book on *International Health* was published in 1952

Beginning with a brief summary of the evolution of international health since the first international Sanitary Conference in 1851, in which tribute is paid to its predecessor organisations, rather more space is given to the establishment of W H O The bulk of the book is a plain factual description of its work under some twenty "functional" headings There are 13 useful appendices giving tabular information on such matters as expert panels, staff, and finance, and many good illustrations and maps It suffers from the defect of most official publications (except the Authorised Version of the Bible) in that neither by phrase, style, or presentation does it do much to help the reader to see the drama of achievement behind the official prose This is perhaps unavoidable, but the absence of a bibliography and adequate references is less excusable A spot check of the index also revealed some gaps Nevertheless, this is an important publication and gives an accurate and adequate account of an expanding and successful ten years Though hardly comparable to the conterminous first ten years of the National Health Service, they have been impressive, particularly when one remembers that for every £ that the whole world spends on W H O, we spend on the N H S over £70

The Strategy of Chemotherapy

8th Symposium of the Society for General Microbiology Editors S T COWAN and E ROWATT London Cambridge University Press 1958 Pp 360 35s

THE chemotherapeutic agents and antibiotics in clinical use have not been designed in any rational scientific way The failure of the logical approach to the chemotherapy of infections is largely due to lack of detailed information about the metabolism of both the invader and the host In this symposium, organised by Dr E F Gale, the 16 contributions review present-day knowledge of this subject and speculate on the lines along which future research might be usefully directed

Prof Robert Knox believes that it would be helpful to consider the strategy of chemotherapy at three different levels the fundamental level, the level of the interactions between microorganisms and the individual host, and the epidemiological level This useful concept is well developed in an article that integrates these different approaches As he points out "it is often difficult for workers in one branch to understand the thoughts or even the language of workers in other branches"

The rest of the book is concerned with fundamental problems It is a pity that there is only the briefest reference to the contribution made by bacterial genetics to our understanding of the mechanisms of drug resistance Separate and detailed consideration is given to bacterial-cell-wall structure and the way chemotherapeutic agents may interfere with its integrity, to similarities and differences in energy-supplying reactions and protein synthesis in microorganisms and host cells, to the action of metal-binding agents, to the design of antimetabolites, to the selective inhibition of virus multiplication and lethal synthesis, and to chemotherapeutic synergy in its widest sense The topics covered from the biochemical viewpoint are therefore numerous and varied, throughout, the importance of and the reasons for selective toxicity are stressed

Full of well-documented information and useful references, the book will provide research-workers with plenty of ideas Its title, however, is perhaps rather misleading It does not deal with strategy at the clinical level, and readers who turn to it with that in mind may find evaluation of biochemical problems rather hard going

Basic Cardiology

T E GUMPERT, M B, F R C P, physician, Royal Hospital, Sheffield, and Jessop Hospital for Women, Sheffield Bristol John Wright 1958 Pp 176 25s

Dr Gumpert has arranged his valuable lectures on cardiology in a small monograph to bridge the gap between the specialised textbooks and the concentrated account found in more general books It is full of common sense and very readable Indeed, some readers may wonder whether common sense has not in places gone too far, at the cost of neglecting physiological and pathological principles, particularly in the chapter on congenital heart-disease Cyanosis in pulmonary stenosis is attributed partly to the degree of pulmonary obstruction interfering with oxygenation, and the left-to-right shunt in atrial septal defect is thought to be due to gravity

In a controversial chapter on systolic murmurs most innocent systolic murmurs are attributed to functional mitral regurgitation It ends with a question "When is a murmur not a murmur? A murmur is not a murmur when it is the only abnormality which can be found in the course of a full cardiological investigation in a patient who is entirely without symptoms" This may be dangerous teaching, for such a murmur might be a clue to a high output state, or to slight valve disease, unimportant in itself, but a possible root for bacterial endocarditis

Psychobiology

A Science of Man ADOLF MEYER M D, late Henry Phipps professor of psychiatry, Johns Hopkins University Compiled and edited by EUNICE E WINTERS and ANNA MAE BOWERS Springfield, Ill Charles C Thomas Oxford Blackwell Scientific Publications 1957 Pp 257 50s

THE first Salmon memorial lecture was delivered by Adolf Meyer in April, 1932 He subsequently revised the lectures for publication but had not completed the task when he died Miss Winters and Miss Bowers, who helped him in the preparation of this and other writings, undertook the heavy work of selecting, from the abundant material which he left, an adequate and telling exposition of his basic ideas "Respect for the Meyerian language and style" was uppermost in their minds, and Meyer wrote a peculiarly involved English, full of abstract nouns, which did no justice to the vigour of his thought and to the wide experience on which his generalisations were founded His old pupils will read these lectures with keen appreciation and a grateful recollection of what they owe to this great teacher, but it is doubtful whether many other readers will penetrate the thicket of words to find the wisdom hidden in them The editors fortunately provide an appendix in which many of the terms used by Meyer are defined and their meaning is amplified

The Heinemann Series on Sex Education (I Parents' Privilege II. A Story About You III What's Happening to Me? IV Learning About Love V Sex Facts and Attitudes London Heinemann Medical Books 1958 Each vol 7s 6d) —These small books, each of 60–80 pages, do not really form a series, in the sense that one leads to the next, but are intended to give information and advice on sexual anatomy and physiology, and the problems of behaviour and conduct arising from sex, to parents of children and to young people of different ages There is much overlapping The information given by the authors, Marion O Lerrigo and Helen Southard, is accurate and the advice sane and not over-emphatic The familiar diagrams probably convey their meaning, other illustrations fall below the standard of the letterpress The transatlantic origin of the books is apparent but not obtrusive (dating, petting, and necking have no inverted commas) How far early familiarity with pelvic anatomy and physiology will make for happier love-making, marriage, and parenthood is anyone's guess, but if they are wanted here are the facts

THE LANCET

LONDON 26 JULY 1958

A Memorable Experiment

When Richard Bright in 1836 called attention to the association between enlargement of the heart and chronic disease of the kidney, he was in effect asking the first of a series of questions which have taxed the resources of subsequent generations of students For over a hundred years progress, depending as it did on observation, inference, and intuition, was inevitably slow, but it nevertheless became clear that, while high blood-pressure could derive from demonstrable kidney disease, it could also occur in its absence The later recognition that this *essential* hypertension could cause renal damage did nothing to simplify the task of those who were patiently trying to bring order out of chaos The year 1933 witnessed an abrupt increase in both the breadth and the tempo of research, for it was in that year that H F Goldblatt, in a historic experiment, showed that in animals simply constricting both renal arteries or one renal artery after excision of the opposite kidney produced a form of sustained hypertension which tallied in most essential respects with the disease in man To mark the 25th anniversary of this experiment the University of Michigan organised a conference on Basic Mechanisms of Arterial Hypertension, at which Dr Goldblatt was guest of honour The proceedings of this conference have now been published in a special issue of *Circulation* [1]

The first, and obvious, conclusion that accrued from Goldblatt's work was that the hypertension that arises in the course of structural disease of the kidney may be attributed to impedance of the circulation The next followed quickly on the discovery that in some species, notably the rat,[2] permanent hypertension could be caused by constriction of only one renal artery Such hypertension was found to be followed by the appearance in the opposite kidney of acute arterial necrosis and other lesions characteristic of malignant hypertension which had previously been regarded as inflammatory, and this strengthened the concept of malignant hypertension and simplified the classification of Bright's disease [3] The suggestion that these lesions in the rat are due to spontaneous periarteritis nodosa [1] or pyelonephritis [5] overlooks the fact that they are invariably absent from the "clamped" kidney Likewise the view that hypertension causes arterial necrosis only in the presence of renal excretory failure [5] is not consistent with clinical or experimental facts [6] The work already mentioned also strengthened the clinical suspicion that unilateral renal disease might underlie some cases of hypertension in man, and it is now generally recognised that severe hypertension may occasionally arise in this way and may be dramatically cured, even in the malignant phase, by nephrectomy provided that the primary renal disease is strictly unilateral and that the condition is recognised before significant secondary hypertensive damage has developed in the opposite kidney The detection of this unilateral renal disease is often extremely difficult, for it may take many different forms, from postoperative stenosis of a ureter [7] to pyelonephritis set up by habitual failure to empty the bladder more than once a day [8]

Another early outcome of Goldblatt's experiment was the rediscovery in the normal kidney of the pressor substance renin,[9] [10] which had lain buried in the literature for forty years Renin was soon found to be an enzyme [9] producing the polypeptide hypertensin Subsequent developments in chemical technique have made possible first the identification of the inert decapeptide,[11] then the elucidation of the structure of the active octapeptide,[12] and finally the synthesis of this highly active substance which contains as much as 50,000 pressor units per milligramme of nitrogen [13] [14] Whether overproduction of renin is responsible for Goldblatt hypertension is still not conclusively proven, but the evidence is very suggestive The strongest evidence relates to the fact that renin is a protein and can be used to prepare a highly specific antibody In animals with renal hypertension passive or active immunity conferred by this antirenin is accompanied by pronounced lowering of the blood-pressure [15] Renin and more recently hypertensin [16] have also been demonstrated in the blood after constriction of the renal artery Hypertension has been maintained for as long as seventeen days in rabbits by continuous intravenous injection of renin,[17] and when such an infusion is discontinued the hypertension persists for about as long as it does when a clip is removed from a renal artery [18]—that is, about four hours A further point relates to the effect of pregnancy During pregnancy in the normal animal the reactivity to renin is lowered,[19] and in rats with Goldblatt hypertension the blood-pressure falls progressively [19] [20] It has recently been shown that these two changes are closely related in time [21] The reactivity to hypertensin is not altered in pregnancy [22] The renin hypothesis will not, of course, account for the hypertension which follows total nephrectomy Nor is it clear why the presence of normal kidney tissue tends to mitigate renal hypertension On the other hand, no simple explanation of renoprival hypertension will explain why constricting one renal artery causes hypertension while excising one kidney

Reviews of Books

The First Ten Years of the World Health Organization

Geneva WHO 1958 Pp 538 To be had from HM Stationery Office 20s (paper backed), 25s (cloth)

IT was natural and proper that the World Health Organisation should celebrate the first ten years of its existence with a commemorative volume Apart from its own official reports and proceedings, no account of its work as a whole has been written since Goodman's more general and historical book on *International Health* was published in 1952

Beginning with a brief summary of the evolution of international health since the first international Sanitary Conference in 1851, in which tribute is paid to its predecessor organisations, rather more space is given to the establishment of WHO The bulk of the book is a plain factual description of its work under some twenty "functional" headings There are 13 useful appendices giving tabular information on such matters as expert panels, staff, and finance, and many good illustrations and maps It suffers from the defect of most official publications (except the Authorised Version of the Bible) in that neither by phrase, style, or presentation does it do much to help the reader to see the drama of achievement behind the official prose This is perhaps unavoidable, but the absence of a bibliography and adequate references is less excusable A spot check of the index also revealed some gaps Nevertheless, this is an important publication and gives an accurate and adequate account of an expanding and successful ten years Though hardly comparable to the conterminous first ten years of the National Health Service, they have been impressive, particularly when one remembers that for every £ that the whole world spends on WHO, we spend on the NHS over £70

The Strategy of Chemotherapy

8th Symposium of the Society for General Microbiology Editors S T COWAN and E ROWATT London Cambridge University Press 1958 Pp 360 35s

THE chemotherapeutic agents and antibiotics in clinical use have not been designed in any rational scientific way The failure of the logical approach to the chemotherapy of infections is largely due to lack of detailed information about the metabolism of both the invader and the host In this symposium, organised by Dr E F Gale, the 16 contributions review present-day knowledge of this subject and speculate on the lines along which future research might be usefully directed

Prof Robert Knox believes that it would be helpful to consider the strategy of chemotherapy at three different levels the fundamental level, the level of the interactions between microorganisms and the individual host, and the epidemiological level This useful concept is well developed in an article that integrates these different approaches As he points out "it is often difficult for workers in one branch to understand the thoughts or even the language of workers in other branches"

The rest of the book is concerned with fundamental problems It is a pity that there is only the briefest reference to the contribution made by bacterial genetics to our understanding of the mechanisms of drug resistance Separate and detailed consideration is given to bacterial-cell-wall structure and the way chemotherapeutic agents may interfere with its integrity, to similarities and differences in energy-supplying reactions and protein synthesis in microorganisms and host cells, to the action of metal-binding agents, to the design of antimetabolites, to the selective inhibition of virus multiplication and lethal synthesis, and to chemotherapeutic synergy in its widest sense The topics covered from the biochemical viewpoint are therefore numerous and varied, throughout, the importance of and the reasons for selective toxicity are stressed

Full of well-documented information and useful references, the book will provide research-workers with plenty of ideas Its title, however, is perhaps rather misleading It does not deal with strategy at the clinical level, and readers who turn to it with that in mind may find evaluation of biochemical problems rather hard going

Basic Cardiology

T E GUMPERT, M B, F R C P, physician, Royal Hospital Sheffield, and Jessop Hospital for Women, Sheffield Bristol John Wright 1958 Pp 176 25s

Dr Gumpert has arranged his valuable lectures on cardiology in a small monograph to bridge the gap between the specialised textbooks and the concentrated account found in more general books It is full of common sense and very readable Indeed, some readers may wonder whether common sense has not in places gone too far, at the cost of neglecting physiological and pathological principles, particularly in the chapter on congenital heart-disease Cyanosis in pulmonary stenosis is attributed partly to the degree of pulmonary obstruction interfering with oxygenation, and the left-to-right shunt in atrial septal defect is thought to be due to gravity

In a controversial chapter on systolic murmurs most innocent systolic murmurs are attributed to functional mitral regurgitation It ends with a question "When is a murmur not a murmur? A murmur is not a murmur when it is the only abnormality which can be found in the course of a full cardiological investigation in a patient who is entirely without symptoms" This may be dangerous teaching, for such a murmur might be a clue to a high output state, or to slight valve disease, unimportant in itself, but a possible root for bacterial endocarditis

Psychobiology

A Memorable Experiment

When RICHARD BRIGHT in 1836 called attention to the association between enlargement of the heart and chronic disease of the kidney, he was in effect asking the first of a series of questions which have taxed the resources of subsequent generations of students For over a hundred years progress, depending as it did on observation, inference, and intuition, was inevitably slow, but it nevertheless became clear that, while high blood-pressure could derive from demonstrable kidney disease, it could also occur in its absence The later recognition that this *essential* hypertension could cause renal damage did nothing to simplify the task of those who were patiently trying to bring order out of chaos The year 1933 witnessed an abrupt increase in both the breadth and the tempo of research, for it was in that year that H F. GOLDBLATT, in a historic experiment, showed that in animals simply constricting both renal arteries or one renal artery after excision of the opposite kidney produced a form of sustained hypertension which tallied in most essential respects with the disease in man To mark the 25th anniversary of this experiment the University of Michigan organised a conference on Basic Mechanisms of Arterial Hypertension, at which Dr GOLDBLATT was guest of honour The proceedings of this conference have now been published in a special issue of *Circulation* [1]

The first, and obvious, conclusion that accrued from GOLDBLATT's work was that the hypertension that arises in the course of structural disease of the kidney may be attributed to impedance of the circulation The next followed quickly on the discovery that in some species, notably the rat,[2] permanent hypertension could be caused by constriction of only one renal artery Such hypertension was found to be followed by the appearance in the opposite kidney of acute arterial necrosis and other lesions characteristic of malignant hypertension which had previously been regarded as inflammatory, and this strengthened the concept of malignant hypertension and simplified the classification of Bright's disease [3] The suggestion that these lesions in the rat are due to spontaneous periarteritis nodosa [4] or pyelonephritis [5] overlooks the fact that they are invariably absent from the "clamped" kidney Likewise the view that hypertension causes arterial necrosis only in the presence of renal excretory failure [5] is not consistent with clinical or experimental facts [6] The work already mentioned also strengthened the clinical suspicion that unilateral renal disease might underlie some cases of hypertension in man, and it is now generally recognised that severe hypertension may occasionally arise in this way and may be dramatically cured, even in the malignant phase, by nephrectomy provided that the primary renal disease is strictly unilateral and that the condition is recognised before significant secondary hypertensive damage has developed in the opposite kidney The detection of this unilateral renal disease is often extremely difficult, for it may take many different forms, from postoperative stenosis of a ureter [7] to pyelonephritis set up by habitual failure to empty the bladder more than once a day [8]

Another early outcome of GOLDBLATT's experiment was the rediscovery in the normal kidney of the pressor substance renin,[9, 10] which had lain buried in the literature for forty years Renin was soon found to be an enzyme [9] producing the polypeptide hypertensin. Subsequent developments in chemical technique have made possible first the identification of the inert decapeptide,[11] then the elucidation of the structure of the active octapeptide,[12] and finally the synthesis of this highly active substance which contains as much as 50,000 pressor units per milligramme of nitrogen [13, 14] Whether overproduction of renin is responsible for Goldblatt hypertension is still not conclusively proven, but the evidence is very suggestive The strongest evidence relates to the fact that renin is a protein and can be used to prepare a highly specific antibody In animals with renal hypertension passive or active immunity conferred by this antirenin is accompanied by pronounced lowering of the blood-pressure [15] Renin and more recently hypertensin [16] have also been demonstrated in the blood after constriction of the renal artery Hypertension has been maintained for as long as seventeen days in rabbits by continuous intravenous injection of renin,[17] and when such an infusion is discontinued the hypertension persists for about as long as it does when a clip is removed from a renal artery [18]—that is, about four hours A further point relates to the effect of pregnancy During pregnancy in the normal animal the reactivity to renin is lowered,[19] and in rats with Goldblatt hypertension the blood-pressure falls progressively [19, 20] It has recently been shown that these two changes are closely related in time [21] The reactivity to hypertensin is not altered in pregnancy [22] The renin hypothesis will not, of course, account for the hypertension which follows total nephrectomy Nor is it clear why the presence of normal kidney tissue tends to mitigate renal hypertension On the other hand, no simple explanation of renoprival hypertension will explain why constricting one renal artery causes hypertension while excising one kidney

Reviews of Books

The First Ten Years of the World Health Organization

Geneva W H O 1958 Pp 538 To be had from H M Stationery Office 20s (paper backed), 25s (cloth)

IT was natural and proper that the World Health Organisation should celebrate the first ten years of its existence with a commemorative volume Apart from its own official reports and proceedings, no account of its work as a whole has been written since Goodman's more general and historical book on *International Health* was published in 1952

Beginning with a brief summary of the evolution of international health since the first international Sanitary Conference in 1851, in which tribute is paid to its predecessor organisations, rather more space is given to the establishment of W H O The bulk of the book is a plain factual description of its work under some twenty "functional" headings There are 13 useful appendices giving tabular information on such matters as expert panels, staff, and finance, and many good illustrations and maps It suffers from the defect of most official publications (except the Authorised Version of the Bible) in that neither by phrase, style, or presentation does it do much to help the reader to see the drama of achievement behind the official prose This is perhaps unavoidable, but the absence of a bibliography and adequate references is less excusable A spot check of the index also revealed some gaps Nevertheless, this is an important publication and gives an accurate and adequate account of an expanding and successful ten years Though hardly comparable to the conterminous first ten years of the National Health Service, they have been impressive, particularly when one remembers that for every £ that the whole world spends on W H O, we spend on the N H S over £70

The Strategy of Chemotherapy

8th Symposium of the Society for General Microbiology Editors S T COWAN and E ROWATT London Cambridge University Press 1958 Pp 360 35s

THE chemotherapeutic agents and antibiotics in clinical use have not been designed in any rational scientific way The failure of the logical approach to the chemotherapy of infections is largely due to lack of detailed information about the metabolism of both the invader and the host In this symposium, organised by Dr E F Gale, the 16 contributions review present-day knowledge of this subject and speculate on the lines along which future research might be usefully directed

Prof Robert Knox believes that it would be helpful to consider the strategy of chemotherapy at three different levels the fundamental level, the level of the interactions between microorganisms and the individual host, and the epidemiological level This useful concept is well developed in an article that integrates these different approaches As he points out " it is often difficult for workers in one branch to understand the thoughts or even the language of workers in other branches "

The rest of the book is concerned with fundamental problems It is a pity that there is only the briefest reference to the contribution made by bacterial genetics to our understanding of the mechanisms of drug resistance Separate and detailed consideration is given to bacterial-cell-wall structure and the way chemotherapeutic agents may interfere with its integrity, to similarities and differences in energy-supplying reactions and protein synthesis in microorganisms and host cells, to the action of metal-binding agents, to the design of antimetabolites, to the selective inhibition of virus multiplication and lethal synthesis, and to chemotherapeutic synergy in its widest sense The topics covered from the biochemical viewpoint are therefore numerous and varied, throughout, the importance of and the reasons for selective toxicity are stressed

Full of well-documented information and useful references, the book will provide research-workers with plenty of ideas Its title, however, is perhaps rather misleading It does not deal with strategy at the clinical level, and readers who turn to it with that in mind may find evaluation of biochemical problems rather hard going

Basic Cardiology

T E GUMPERT, M B, F R C P, physician, Royal Hospital, Sheffield, and Jessop Hospital for Women, Sheffield Bristol *John Wright 1958 Pp 176 25s*

Dr Gumpert has arranged his valuable lectures on cardiology in a small monograph to bridge the gap between the specialised textbooks and the concentrated account found in more general books It is full of common sense and very readable Indeed, some readers may wonder whether common sense has not in places gone too far, at the cost of neglecting physiological and pathological principles, particularly in the chapter on congenital heart-disease Cyanosis in pulmonary stenosis is attributed partly to the degree of pulmonary obstruction interfering with oxygenation, and the left-to-right shunt in atrial septal defect is thought to be due to gravity

In a controversial chapter on systolic murmurs most innocent systolic murmurs are attributed to functional mitral regurgitation It ends with a question " When is a murmur not a murmur? A murmur is not a murmur when it is the only abnormality which can be found in the course of a full cardiological investigation in a patient who is entirely without symptoms " This may be dangerous teaching, for such a murmur might be a clue to a high output state, or to slight valve disease, unimportant in itself, but a possible root for bacterial endocarditis

Psychobiology

A Science of Man ADOLF MEYER M D, late Henry Phipps professor of psychiatry, Johns Hopkins University Compiled and edited by EUNICE E WINTERS and ANNA MAE BOWERS Springfield, Ill Charles C Thomas Oxford Blackwell Scientific Publications 1957 Pp 257 50s

THE first Salmon memorial lecture was delivered by Adolf Meyer in April, 1932 He subsequently revised the lectures for publication but had not completed the task when he died Miss Winters and Miss Bowers, who helped him in the preparation of this and other writings, undertook the heavy work of selecting, from the abundant material which he left, an adequate and telling exposition of his basic ideas " Respect for the Meyerian language and style " was uppermost in their minds, and Meyer wrote a peculiarly involved English, full of abstract nouns, which did no justice to the vigour of his thought and to the wide experience on which his generalisations were founded His old pupils will read these lectures with keen appreciation and a grateful recollection of what they owe to this great teacher, but it is doubtful whether many other readers will penetrate the thicket of words to find the wisdom hidden in them The editors fortunately provide an appendix in which many of the terms used by Meyer are defined and their meaning is amplified

---

The Heinemann Series on Sex Education (I Parents' Privilege II A Story About You III What's Happening to Me? IV Learning About Love V Sex Facts and Attitudes London Heinemann Medical Books 1958 Each vol 7s 6d) —These small books, each of 60–80 pages, do not really form a series, in the sense that one leads to the next, but are intended to give information and advice on sexual anatomy and physiology, and the problems of behaviour and conduct arising from sex, to parents of children and to young people of different ages There is much overlapping The information given by the authors, Marion O Lerrigo and Helen Southard, is accurate and the advice sane and not over-emphatic The familiar diagrams probably convey their meaning, other illustrations fall below the standard of the letterpress The transatlantic origin of the books is apparent but not obtrusive (dating, petting, and necking have no inverted commas) How far early familiarity with pelvic anatomy and physiology will make for happier love-making, marriage, and parenthood is anyone's guess, but if they are wanted here are the facts

THE LANCET

LONDON 26 JULY 1958

A Memorable Experiment

When RICHARD BRIGHT in 1836 called attention to the association between enlargement of the heart and chronic disease of the kidney, he was in effect asking the first of a series of questions which have taxed the resources of subsequent generations of students For over a hundred years progress, depending as it did on observation, inference, and intuition, was inevitably slow, but it nevertheless became clear that, while high blood-pressure could derive from demonstrable kidney disease, it could also occur in its absence The later recognition that this *essential* hypertension could cause renal damage did nothing to simplify the task of those who were patiently trying to bring order out of chaos The year 1933 witnessed an abrupt increase in both the breadth and the tempo of research, for it was in that year that H F GOLDBLATT, in a historic experiment, showed that in animals simply constricting both renal arteries or one renal artery after excision of the opposite kidney produced a form of sustained hypertension which tallied in most essential respects with the disease in man To mark the 25th anniversary of this experiment the University of Michigan organised a conference on Basic Mechanisms of Arterial Hypertension, at which Dr GOLDBLATT was guest of honour The proceedings of this conference have now been published in a special issue of *Circulation*[1]

The first, and obvious, conclusion that accrued from GOLDBLATT's work was that the hypertension that arises in the course of structural disease of the kidney may be attributed to impedance of the circulation The next followed quickly on the discovery that in some species, notably the rat,[2] permanent hypertension could be caused by constriction of only one renal artery Such hypertension was found to be followed by the appearance in the opposite kidney of acute arterial necrosis and other lesions characteristic of malignant hypertension which had previously been regarded as inflammatory, and this strengthened the concept of malignant hypertension and simplified the classification of Bright's disease[3] The suggestion that these lesions in the rat are due to spontaneous periarteritis nodosa[4] or pyelonephritis[5] overlooks the fact that they are invariably absent from the " clamped " kidney Likewise the view that hypertension causes arterial necrosis only in the presence of renal excretory failure[5] is not consistent with clinical or experimental facts[6] The work already mentioned also strengthened the clinical suspicion that unilateral renal disease might underlie some cases of hypertension in man, and it is now generally recognised that severe hypertension may occasionally arise in this way and may be dramatically cured, even in the malignant phase, by nephrectomy provided that the primary renal disease is strictly unilateral and that the condition is recognised before significant secondary hypertensive damage has developed in the opposite kidney The detection of this unilateral renal disease is often extremely difficult, for it may take many different forms, from postoperative stenosis of a ureter[7] to pyelonephritis set up by habitual failure to empty the bladder more than once a day[8]

Another early outcome of GOLDBLATT's experiment was the rediscovery in the normal kidney of the pressor substance renin,[9] [10] which had lain buried in the literature for forty years Renin was soon found to be an enzyme[9] producing the polypeptide hypertensin Subsequent developments in chemical technique have made possible first the identification of the inert decapeptide,[11] then the elucidation of the structure of the active octapeptide,[12] and finally the synthesis of this highly active substance which contains as much as 50,000 pressor units per milligramme of nitrogen[13] [14] Whether overproduction of renin is responsible for Goldblatt hypertension is still not conclusively proven, but the evidence is very suggestive The strongest evidence relates to the fact that renin is a protein and can be used to prepare a highly specific antibody In animals with renal hypertension passive or active immunity conferred by this antirenin is accompanied by pronounced lowering of the blood-pressure[15] Renin and more recently hypertensin[16] have also been demonstrated in the blood after constriction of the renal artery Hypertension has been maintained for as long as seventeen days in rabbits by continuous intravenous injection of renin,[17] and when such an infusion is discontinued the hypertension persists for about as long as it does when a clip is removed from a renal artery[18]—that is, about four hours A further point relates to the effect of pregnancy During pregnancy in the normal animal the reactivity to renin is lowered,[19] and in rats with Goldblatt hypertension the blood-pressure falls progressively[19] [20] It has recently been shown that these two changes are closely related in time[21] The reactivity to hypertensin is not altered in pregnancy[22] The renin hypothesis will not, of course, account for the hypertension which follows total nephrectomy Nor is it clear why the presence of normal kidney tissue tends to mitigate renal hypertension On the other hand, no simple explanation of renoprival hypertension will explain why constricting one renal artery causes hypertension while excising one kidney does not On the whole the prevailing opinion is that renal and renoprival hypertension are not directly related to one another

To turn to a more fundamental question Is essential hypertension a form of renal hypertension? **Goldblatt**'s experiment was designed to test the hypothesis that the structural arterial changes observed at necropsy were not the result but the cause of the hypertension, and he has always maintained that his results provide general support for the hypothesis Renal and essential hypertension resemble one another very closely in many respects, as **Goldblatt** points out [4], and this certainly suggests that a common mechanism may be at work Moreover, there is recent evidence that the hypertensin content of human blood is raised slightly in benign hypertension and very greatly in malignant hypertension [16] Nevertheless there is singularly little evidence either from biopsy or postmortem material that mild or early essential hypertension is attended by structural disease of the renal arteries Almost all workers therefore regard the arterial lesions observed at necropsy as secondary to the hypertension, and hold that any primary narrowing of the arterial bed must be functional The distinction is important, because while increased tone of the renal arterial tree is potentially reversible organic narrowing is certainly not

If essential hypertension is in fact renal in origin—and conclusive evidence is still lacking—the most important outstanding problem will be to find out the cause or causes of the increase in renal arterial tone

Metals and Plastics in Intraocular Surgery

Ophthalmic surgeons have been keenly exploring the potentialities of implanted inert materials, especially plastics—notably for the purpose of correcting refractive errors by means of intraocular artificial lenses **Harold Ridley**, the first in this field, in 1951 described his method for overcoming the visual defect in cases of aphakia by means of an acrylic lens inserted behind the iris and in front of an intact posterior-lens capsule [1 2] By 1953, however, it was evident that this technique had its limitations The artificial lens had to be inserted at the same time as an extracapsular cataract extraction was performed so that there was no means of checking the aphakic correction before the implant was inserted, and furthermore patients in whom the posterior capsule had been divided or had been removed were not eligible Perceiving the possibilities of this technique, other workers, including **Strampelli** [3] in Italy, **Schreck** [4] in Germany, and **Barraquer Moner** [5] in Spain, evolved an implant placed in front of the iris and behind the cornea, with feet wedged in the anterior-chamber angles and carrying a central optical portion, the correction of which could be modified to suit the requirements of the individual case An important advantage of the anterior-chamber implant is that it can, and indeed should, be inserted after cataract surgery has been completed, thus enabling the surgeon to minimise the operative trauma to the eye at each session Trauma to the eye has been further reduced by the introduction of new methods of sterilising the implants While polymethyl methacrylate (or "acrylic") is completely inert in the tissues, with the original method of sterilisation by cetrimide small quantities of this irritant were adsorbed by the implant, subsequently leaking out into and irritating the eye Sterilisation by ultraviolet light is open to the objection that it degrades the parent chemical, producing an irritant monomer near the surface of the implant, which would have the same effect as cetrimide **Frederick Ridley** [6] has devised a simple and effective method of sterilising acrylic implants with 10% sodium hydroxide

Uniocular cataract and uniocular aphakia are by no means rare The disability in such cases is considerable, unaided vision is usually less than 3/60, and the patient is denied binocular vision In children especially, the useless eye will tend to converge or diverge, and an ugly squint-combines with a functionless eye to give the patient a sense of inferiority which may produce serious psychological trauma Attempts to use a normal eye with an aphakic one by means of spectacles fail because of aniseikonia amounting to about 30% A contact lens for the aphakic eye will reduce the disparity in image size to about 10%, but many patients cannot tolerate even this amount of aniseikonia An anterior-chamber implant reduces the figure to about 3–5%, which is tolerable

At this year's Oxford Ophthalmological Congress, **Choyce** [7] described 60 cases of uniocular aphakia treated with acrylic anterior-chamber implants He stressed that cataract surgery must be completed at least six weeks before implantation is undertaken In most of **Choyce**'s cases binocular vision was restored and in the remainder alternating suppression developed, accordingly diplopia was not experienced even by patients who had previously had diplopia with a contact lens About a third of his cases had resulted from trauma, and the length of time which had elapsed since the injury was of no consequence, 6/6 vision was restored to some patients as long as fifty years after injury had caused a cataract If the injury had occurred in early childhood amblyopia ex anopsia was inevitable, and limited the visual result, but patients appreciated the restoration of even slight unaided vision to what they had come to regard as a useless eye Another third of **Choyce**'s cases were of uniocular senile cataract in patients over 50 years of age, and after operation these too had the use of the two eyes together, instead of having to decide which eye to use The remaining patients had either heterochromic cyclitis (all did well) or congenital uniocular cataract (some did well) It is only two years since the first implantation in this series, and it remains to be seen whether **Choyce**'s results stand the test of time and are confirmed by other surgeons, but it seems likely that the problem of the patient with uniocular aphakia who cannot tolerate a contact lens has been solved

Theoretically, anterior-chamber implants can be put to other uses—for example, the correction of high

myopia and other refractive errors in phakic eyes An opaque implant could be used to enforce occlusion of the good eye in a squinting child who would not tolerate ordinary methods of occlusion—and, after all, removal of these implants is simple But merely opening the eye, let alone inserting so large a foreign body, must substantially increase the chances of the lens becoming cataractous, and at present there is no justification for inserting anterior-chamber implants into eyes which retain their own crystalline lenses In cases of glaucoma fistulising operations are usually successful in White patients In the Negro they almost always fail, and much work has been done, especially by STONE et al[8] in the U S.A., on the use of polyethylene wicks and tubes and of tantalum wire Efforts to replace vitreous by non-living materials have not so far been successful, transfer of human vitreous seems to offer the best prospect of success at present.[9-11]

The possibility of burying implants incompletely within the eyeball has been closely studied in rabbits by STONE et al[12] in their search for an artificial cornea Edge-to-edge union between cornea and acrylic cannot be induced, but if the cornea is split from limbus to limbus, just superficial to Descemet's membrane, an acrylic disc can be slid into this interlamellar space. These discs are well tolerated, later a smaller disc of overlying cornea can be removed by trephining, and still later a similar posterior disc removed via the anterior chamber Such an opening will remain patent until the natural death of the animal This ingenious technique provides an opportunity to study the reaction of the corneal cells to incompletely buried acrylic but clinically it is not likely to replace the use of human donor material for cases requiring conventional lamellar or full-thickness keratoplasties Nevertheless TUDOR THOMAS[13] has described a penetrating acrylic implant retained in place by an overlying lamellar corneal graft, and has by this means been able to help patients whose eye condition was extremely unfavourable for ordinary methods of corneal transplantation

What Hospitals for Children?

Professor ILLINGWORTH's article this week shows once more how much care and thought are needed if the child in hospital is to be treated as he should be Can anyone reading it be satisfied with a system in which many children are still looked after by hospital doctors and nurses to whom pædiatrics is a sideline? Reacting not unreasonably from the trend towards making everything a specialty, some physicians and surgeons would defend their right to go on treating both old and young, even side by side, and of course it is true that skill with the one phase of life does not exclude skill with the other But the child is not just a small adult, his management unquestionably requires both special study and special experience, and when he is seriously ill his survival may depend on treatment by a team which is fully accustomed to some technique peculiar to his age. (The treatment of œsophageal atresia in the newborn, described by Dr HELLINGS and her colleagues on p 182, is a case in point.) Whenever his disease is complex or difficult, the child will have a better chance if the doctor in charge of him is in a position to get help from surgeons, pathologists, radiologists, and other specialists who have given much attention to the pædiatric side of their specialty and have come to think in terms of children

One essential, then, is a staff which, at all levels and in all departments, is (as the Royal College of Physicians[1] put it) "attuned to the special needs of the sick child", and the other is a staff large enough to include all the necessary talents Both these conditions can be fulfilled in a special children's hospital, or in a big children's block forming part of a general hospital, but they are not fulfilled in most of the hospitals up and down the country to which so many children are admitted From the medical standpoint, only the large pædiatric unit can be fully efficient, and, if there is a surplus of children's beds, it is the small units in general hospitals that should be eliminated—not the children's hospitals Some of the latter, though they appear relatively small and inconvenient to the administrator, are relatively large and convenient for the children, and until a hospital authority can provide something equally large and convenient, *for children*, as part of a general hospital, it should leave them alone—or try to strengthen them

As things are today, pædiatricians who have beds in both kinds of hospital not uncommonly transfer patients from the general hospital (sometimes a teaching one) to the children's hospital They do this because, for a difficult case, they regard the children's hospital as better—better perhaps for consultation, better for investigation, or better for treatment. In a hospital treating children only, all the departments are adapted specifically to their needs For instance, whereas the laboratory of a general hospital might ask for 5 ml of blood from a vein, in a children's hospital the investigation would be done on 0 5 ml of blood from a heel prick. Again, radiography of the lungs in a general hospital often produces a useless result, the wriggling baby being askew and the film lacking definition (All too often, moreover, the whole baby is unnecessarily exposed to X rays) As a rule, the films produced in a children's hospital, by those who are used to handling the very young, are much superior For treatment, the children's hospital will have teams for managing neonatal obstruction, acute gastroenteritis, metabolic disturbances, and the many other emergencies so difficult to cope with in the absence of an experienced team

Even the everyday nursing of children demands technique and methods quite different from those used for adults, and, as the Royal College of Physicians emphasised, the training for it must be correspondingly specialised In providing such training the children's hospitals have their own kind of success Thus a pædiatrician with beds in a teaching hospital, and also in the children's hospital attached to it, remarked that, though the parent undergraduate hospital attracts students of better education, the nursing care of children is very much better at the children's hospital—the explanation being that the young women there have taken up this work because they particularly want to do it Both the children's hospitals and the larger pædiatric units in general hospitals could usefully give three months' training to many student nurses working for the general register, but only on condition that they have enough fully trained pædiatric nurses to give the teaching, and that the students are regarded for the most part as supernumeraries For such students, doing their general training, a small and poorly staffed children's unit in a general hospital where the handling of children is unsatisfactory affords experience which is rather worse than useless

[1] Children in Hospital Report approved in comitia by the Royal College of Physicians of London and published in The Lancet, 1957, i, 926.

The reasons why there is less demand on children's beds than in 1948 are (1) the physical health of children has improved, (2) their illnesses are often shortened by more effective treatment, (3) probably more of them are treated at home, (4) additional children's wards have been opened in general hospitals, and (5) many children who would previously have gone into children's hospitals and general hospitals now go into fever hospitals—where there are always empty beds We have no recent figures for the distribution of child patients, and in particular we do not know how many are in adult wards, but the returns of one regional board for a day in the autumn of 1955 showed that of the 1568 in children's wards 1082 were " medical ", and that only a little over half of these were under the care of a pædiatrician Of the other 532 medical cases 243 were in fever hospitals Because admission is easy, children nowadays go to such hospitals with pneumonia, meningitis, septicæmia, gastroenteritis, and rheumatism, not to mention a good many undiagnosed conditions ranging from cœliac disease to congenital hæmolytic anæmia Sometimes, of course, the child thus admitted finds medical and nursing care which is fully equal to the occasion, and this journal, like others, has recorded fine work for children which has been done in fever hospitals—as also elsewhere—by physicians who would neither claim to be pædiatricians nor wish to limit themselves by such a title On the other hand, many fever hospitals—including some of the large ones, have poor facilities (e g , in pathology), insufficient nurses, and no arrangements for educating the children while they are in hospital or for following them up when they have left and some of the smaller ones have no resident medical staff To the hard-pressed family doctor, anxious about his young patient, such a hospital's willingness to accept the case has often been a godsend , and very often, as we have said, excellent care has been given despite all the difficulties But the development of fever hospitals as supplementary children's hospitals can scarcely be defended now that there are said to be too many children's beds and some of the children's hospitals are themselves faced with closure Instead of making fever hospitals responsible for children with non-infectious diseases, it would be better to make children's hospitals and general hospitals responsible for fevers—equipping them with units for the purpose, as has been done in the U S A and many Continental countries

In the region we have mentioned, 28 of the hospitals which had children's beds (medical, surgical, ear, nose, and throat) had fewer than 15, and we do not believe that a number like this, or anything like it, permits the formation of a pædiatric group or environment capable of giving the varied yet specialised care that children so often require If the treatment of sick children is to improve, the policy should be not only to discontinue the routine admission of children to adult wards but also to eliminate, progressively, the children's units which are too small to be pædiatrically viable On the positive side, support should be given to the larger units—children's hospitals and big departments in general hospitals The Ministry of Health would set the ball rolling in the right direction if it officially endorsed and made known to administrative bodies the report of the Royal College of Physicians committee,[1] on which it was represented A circular to regional boards could emphasise

1 The need to build up, in each region, a relatively small number of big pædiatric units, fully staffed and fully equipped —with special attention to any children's hospitals, from which will come much of the pædiatric staff of the future As the college suggests, branch outpatient pædiatric departments can be based on these units

2 The need to discontinue the use of fever hospitals for children not suffering from the so-called infectious fevers, to link the fever hospitals with pædiatric hospitals or units,[2] and to arrange eventually for the treatment of these fevers in isolation wards forming part of children's hospitals and general hospitals

3 The need to stop indiscriminate admission of children to adult wards

Where there are more children's beds than an area can use, the units to be closed should be those that are too small to give the special kind of care, the special skills, and the special knowledge which children require —and to which they are entitled no less than adults

Poliomyelitis Vaccination

THE Government's programme of vaccination against poliomyelitis is to be extended from the present age-limit of 15 to 25, a wider range of hospital staff and their families are to be included, and a start is to be made with third injections of people already vaccinated twice This was announced by Mr DEREK WALKER-SMITH in the House of Commons on Monday Those hitherto eligible for vaccination are children born in 1943-57, expectant mothers, general practitioners, and hospital and ambulance staffs and their families At June 30 a total of 6,570,157 had registered, of whom 4,481,837 had received two doses and 856,388 one dose, 1,231,932 were awaiting vaccination The registration-rate for children under 15 at June 30 was 53 6% The number of doses needed to complete registrations was 3,320,252, and 3,766,651 doses were held by local health authorities Of the new groups those aged 15-24 total some 6,250,000 and hospital staffs and families 500,000, and those eligible up to March 31, 1959, for a third injection may total 6,500,000 It is proposed to ask local health authorities to offer as soon as possible third injections to children vaccinated in 1956—about 200,000

Annotations

THE PRINCESS LOUISE

THE Minister has at last said what he now thinks should be done with the Princess Louise (Kensington) Hospital for Children: it should be cut in half, so that the present staff have two wards for pædiatrics while St. Mary's Hospital have the other two for obstetrics and gynæcology. Let us hope that this judgment, like Solomon's, is intended merely to reveal the relative strength of the affections of the claimants, for otherwise it has few merits. True, the division, unlike that of Solomon's baby, is to be temporary, and a couple of years will give time for reflection. But after these years, unfortunately, the hospital, as a children's hospital, may be virtually dead. If we are right in the arguments of our preceding article, the Minister is wrong in reducing a children's hospital of 76 beds to a mixed hospital with less than 40 children's beds. If he thinks that there are too many such beds in the area, the correct policy is to eliminate one or more of the smaller units in general hospitals which cannot give children the full benefit of pædiatric knowledge and training.

The Princess Louise Hospital was built in 1928, at a cost of £75,000 raised mainly within the borough, to meet the needs of the rapidly developing and overcrowded area of North Kensington. In 1945 its board decided that, under a National Health Service, its security, wellbeing, and development would be best secured by joining a teaching hospital, and in 1946 it amalgamated with St. Mary's on the understanding (we are told) that it should retain its name and continue as a children's hospital. About the same time St. Mary's also amalgamated with the Paddington Green Children's Hospital, and ever since then they have had more pædiatric beds than they need for teaching, and fewer beds of other kinds.

Their first proposal in 1949 was to convert their smaller children's hospital (Paddington Green) into a hospital for adults, but this was strongly opposed in the neighbourhood, and since 1955 they have concentrated on the conversion of the Princess Louise, which is thought to be architecturally easier. This, too, aroused opposition, and in November, 1956, the Minister is said to have accepted a solution whereby St. Mary's should allow the Princess Louise to be transferred, as a children's hospital, to the North West Metropolitan Regional Hospital Board, accepting in exchange additional adult beds for teaching purposes in Paddington General or St. Charles' Hospitals. But St. Mary's refused to do this because they rightly wanted their teaching beds to be directly under their own control.

The Minister's new solution of the problem is to allow St. Mary's "to convert two wards at the Princess Louise Hospital for the temporary use of maternity patients pending the provision of the professorial unit [in obstetrics and gynæcology] at St. Mary's Hospital, and to defer a decision on the long term future of Princess Louise Hospital until that unit is nearing completion." He is "satisfied that it is practicable for those entitled to avail themselves of the benefit of the objects of the Princess Louise Hospital for Children to enjoy similar facilities in suitable neighbouring hospitals."

If the Princess Louise Hospital were consistently empty, while units in neighbouring hospitals were full, there would be a case for saying that it is no longer doing its work and can suitably be spared. But that does not seem to be so.

Because of the seasonal fluctuations in demand, bed-occupancy in children's hospitals over the twelve months is bound to be relatively low, and at the Princess Louise admissions were curtailed in 1955 and 1956 by poliomyelitis and throughout 1957 by a *Salmonella typhi-murium* infection. Even so, the following figures are not unsatisfactory:

	Inpatients	*Bed occupancy* %
1946	832	68
1947	939	63
1948	1088	70
1949	1020	75
1950	1211	78
1951	1427	69
1952	1656	71
1953	1758	80
1954	1807	76
1955	1363	75
1956	1726	73
1957	1290	58

Recent uncertainties have already weakened the staff because a number of consultant and other medical vacancies have not been filled, and of course this weakening would continue if the Minister's proposal were fulfilled. But the hospital remains, pædiatrically, in a stronger position than many smaller units. The general-purposes committee of the Kensington Borough Council, which is vigorously opposed to the proposal, refers as follows to grave illness treated in the hospital[1] last winter:

> "We . . . are convinced the Princess Louise Hospital, truncated by the threatened loss of two whole wards, cannot adequately meet the continuing and indeed growing needs of the child population of the area, still less cope with an epidemic such as the recent virulent and rapidly fatal chest complaint in infants known as bronchiolitis. This recent outbreak called for the use of every available cot and bed and at one stage as many as sixteen infants were in oxygen tents at the same time."

The Kensington committee appeals to the Minister to revert to what apparently was his previous plan—namely, that the Princess Louise should be preserved as a children's hospital and be placed (as though its unfortunate amalgamation with St. Mary's had never taken place) under the North-West Metropolitan Regional Hospital Board—or alternatively asks him to attach it to one of the teaching hospitals which has a deficiency rather than a surplus of children's beds. The Minister could scarcely wish to oppose this suggestion if St. Mary's could be induced to make it, and St. Mary's would surely be wise to rid themselves of what has clearly become a very embarrassing problem. To do so they must obtain elsewhere, for a time, the obstetrical and gynæcological beds they will need while their new unit is being built, but, according to the Kensington committee, the regional board is prepared to find these, "possibly by closing the children's beds at St. Charles'," which is close beside the Princess Louise. We hope that, if St. Mary's can count on controlling the borrowed beds, this alternative may prove acceptable.

ANOMALOUS AIR SHADOWS

LUMBAR air encephalography by a technique designed not to alter the intracranial pressure is being increasingly used, as an alternative to ventriculography, in the investigation of intracranial tumours, including those in the posterior fossa.[2] When there is obstruction to the cerebrospinal-fluid pathways, air filling of the ventricles may not take place and the interpretation of the films depends largely on the appearances of the basal cisterns and cerebral sulci. Schechter et al.[3] have reported from the National Hospital, Queen Square, four cases in which there were surprising air shadows. In all four there was an obstructive lesion in the posterior fossa: in one an astrocytoma invading the fourth ventricle, shown at operation and necropsy, in one an intrinsic tumour of the medulla oblongata demonstrated at operation, and in the other two stenosis of the aquaduct of Sylvius shown by

1. *Lancet*, 1958, i, 482.
2. Norlén, G., Wickbom, I. *J. Neurol. Neurosurg. Psychiat.* 1958, 21, 1.
3. Schechter, M. M., Bull, J. W. D., Carey, P. *Brit. J. Radiol.* 1958, 31, 317.

ventriculography In all four patients air encephalography showed abnormally large sulci corporis callosi, and in one the cingulate sulcus was also unusually wide and well outlined In the two tumour cases an unusual shadow was seen just to the left of the third ventricle, this shadow was half-moon shaped in the lateral position, and in the anteroposterior view was situated just to the left of the midline, being rounded medially and drawn out laterally Schechter et al thought that this latter shadow represented a dilated cisterna ambiens and confirmed this by studying the radiological appearances of this cistern in a normal brain and in the necropsy specimen of their first case after pledgets of cotton-wool soaked in radio-opaque material had been placed in the cistern

To elucidate these unexpected appearances further, the Queen Square workers reviewed a hundred normal lumbar encephalograms and a hundred encephalograms of patients in whom there was thought to be cerebral atrophy Unfortunately they do not mention any criteria on which the diagnosis of cerebral atrophy had been made In the normal group some filling of the sulci corporis callosi was shown in five cases and of the cisterna ambiens in ninety-two, but never to the same degree as in the two tumour cases In the cases of cerebral atrophy the sulci corporis callosi were seen in ten cases and the cisterna ambiens in ninety-three, but here again considerable dilatation was never seen Pronounced filling of the sulcus corporis callosi on air encephalography has been reported on four previous occasions in cases of tumour of the posterior fossa, and a case has been described [4] in which there was a shadow similar to those ascribed by Schechter et al to dilatation of one side of the cisterna ambiense associated with a posterior-fossa meningioma Schechter et al do not give any convincing explanation of these surprising encephalographic appearances with obstructive lesions in the posterior fossa, but their observations are of considerable practical importance, as it would be easy to ascribe dilated cerebral sulci and a dilated cisterna ambiens to an atrophic process in the brain, and to omit doing further investigations which might reveal a tumour in the posterior fossa

ACUTE EPIGLOTTITIS

LITTLE has been written about acute epiglottitis, a serious and often fatal disorder of early life Jones and Camps [5] last year called attention to the condition in Great Britain, and Berenberg and Kevy [6] emphasise the need for prompt diagnosis and treatment They report from the Boston Children's Medical Center a series of 42 patients, with ages ranging from three months to fourteen years, in only 1 of whom was the diagnosis made before admission The majority of the children were admitted in the winter and early spring, and *Hæmophilus influenzæ* group B was the predominant but not the only micro-organism producing the clinical picture There was an abrupt onset and rapid evolution of the serious features About half the children had been ill for less than eight hours before admission, and three, who were dead on arrival at hospital, had been ill for less than six hours Patients who could describe their symptoms said that they had extreme pain in the throat and on swallowing The secretions of the upper respiratory tract were retained with copious "puddling" of the pharyngeal mucus and excessive "drooling" Restlessness, irritability, and difficulty in breathing were noted early Hoarseness and a croupy crow occurred in about a third The temperature pulse-rate, and respiratory-rate were all raised Som patients showed a state of shock with pallor and cyanosis Enlarged neck glands were uncommon and pharyngiti was only moderate, but the involvement of the epiglotti was striking and easily seen The tongue must be adequately depressed, and then the inflamed and œdematou epiglottis rises readily into the field of vision, resemblin "a bright red cherry obstructing the pharynx at the bas of the tongue" With the diagnosis made, it must b regarded as presenting an emergency necessitating promp admission to hospital There must be constant and exper observation by medical and nursing staff The chil should be placed in a cool, humidified atmosphere and al preparations made for tracheotomy, which must not b delayed if the patient is cyanotic and obviously in need o oxygen In the Boston series there were no deaths i *children so treated, and the 5 deaths in the whole serie* could, in the opinion of Berenberg and Kevy, have bee prevented by early tracheotomy—a conclusion accordin with that of Jones and Camps In view of the emergency antibiotic therapy must not be delayed for bacteriologica diagnosis The American workers administer chloramphenicol intramuscularly in doses of 100 mg per kg body-weight for the first twenty-four to thirty-six hours and then 50 mg per kg orally if it can be swallowed It i clear that acute epiglottis should always be thought o and sought in acutely developing respiratory distress i childhood The common diagnoses with which the Boston children were referred to hospital included "croup", tracheobronchitis, laryngitis, streptococcal pharyngitis, asthma, and foreign body in the respiratory tract

MEDICAL WOMEN'S CONGRESS

WHEN a group of women doctors met in New York in 1919 to form the Medical Women's International Association, their president was Dr Esther P Lovejoy, and it was Dr Lovejoy, followed by Dr Janet Aitken, the new president, who responded to the toast of The Association at last Monday's banquet (see p 220) This was the concluding event of a large and successful gathering which opened on July 15 with a reception at the senate house of London University, attended by Queen Elizabeth the Queen Mother as Chancellor The subject of the scientific sessions, The Adolescent, was treated from various standpoints—physical, psychological, social, and familial

Miss Josephine Barnes (London) spoke on gynæcological aspects of puberty, Prof M L Chevrel (Rennes) on cancer in adolescents, Prof Sellina Gualco (Rome) on endocrinological disorders of puberty, Dr Alma Morani (U S A) on correction of physical defects, Dr H J A Verhogen (Holland) on sociological and scholastic aspects, Dr Hadassa Heinrich (Israel) on medical examinations in a youth corps, Dr Melitta Mitscherlich (Dusseldorf) on the development of the ego, and Dr Viveka Lagencrantz (Sweden) on psychiatric aspects of adolescence

The British hosts of the Association were the Medical Women's Federation, whose president is now Miss Katharine Lloyd-Williams

Prof G M WISHART, dean of the faculty of medicine of the University of Glasgow, died on July 18

COMMUNITY TREATMENT OF MENTAL ILLNESS *

DUNCAN MACMILLAN
M D , B Sc Edin , F R C P E , D Psych
PHYSICIAN-SUPERINTENDENT,
MAPPERLEY HOSPITAL, NOTTINGHAM

THE isolation of the mental hospital, which was practically absolute before the Mental Treatment Act of 1930, is rapidly disappearing, and more and more psychiatric patients are being treated in the community instead of in the hospital The hospital's first link with the community was the outpatient department Later liaison was gradually established with outside services such as probation departments, industrial medical officers, child-guidance centres, and the Ministry of Labour Social psychiatry continued to grow steadily, but of late years the pace has quickened as more and more community centres, day hospitals, and night hospitals have been opened These have varied in form and setting Some are independent, while some are associated with mental hospitals and some with psychiatric units in general hospitals Some offer domiciliary visits, some do not

PARTIAL COMMUNITY CARE

All these developments are in fact extensions of the work of the outpatient department The day hospital offers a more comprehensive system of aftercare which enables the inpatient to be discharged from hospital earlier and often avoids the need for readmission, while the night hospital is a useful halfway stage where patients can adjust themselves gradually to life and work in the community Day centres and day hospitals offer an alternative to hospital treatment as well as sometimes preventing the need for it, and their group atmosphere is of inestimable value for certain patients They are useful additions to hospital resources and lessen the strain on beds, but they do not necessarily alter the function of the hospital

Other schemes try to relieve the pressure on mental-hospital beds more directly In Amsterdam, for instance, there is a scheme for domiciliary visits and community care run by the city authorities[1] In this country, efforts are being made in different ways It is sometimes said that a community service is only practicable in a compact urban population, but the Worthing[2] experiment shows what can be done in a county area

Though these schemes were usually started with the idea of saving money and hospital beds, experience shows that they have other advantages, and that they allow the patient to be helped in ways outside the scope of inpatient treatment Earlier treatment, prophylactic measures, adjustment of interpersonal relationships, and treatment of the family as a unit all become possible

Most of the community schemes do not cope with all forms of psychiatric illness For instance, patients with chronic psychoses, particularly if they have antisocial reactions, are usually sent to the local mental hospital and pass from the care of the community service Some schemes are more comprehensive, but generally speaking the chronic mental patient is excluded from community treatment once the home situation becomes too strained for him to go on living at home

A Comprehensive Service

The system of community treatment which I believe offers patients the best care at all stages of their illness is a comprehensive service which treats all mental illness, including the chronic psychoses This means that the mental hospital must take an active part in the scheme and is the most practical way of using our existing resources It also means that we must alter our attitude to the chronic patients, and establish a personal relationship with them

In a service of this kind admission to hospital is not restricted It is still promptly available, but it is limited to short-term episodes in a course of treatment which is based on the home Admission and discharge are arranged in a flexible way with a minimum of formality The function of the hospital is altered and modified, so that it becomes only one part, but an essential part, of the service The resources and energies which would otherwise be spent providing long-term residential accommodation for patients can be diverted to domiciliary and community activities The emphasis in the scheme of therapy moves from the hospital to the home, with community treatment playing an important part in all psychiatric illnesses The patient retains his social and economic independence, and the mental hospital, like the general hospital, offers him specialised inpatient treatment when the resources of the home and the domiciliary and community services become temporarily unable to cope with his illness

There is a tendency to regard long-continued hospital treatment as the only possible course in severe long-term psychoses There is a fear that without it antisocial acts would increase, and many people are doubtful how the patient would respond to community influences Yet the aggression of the psychotic is due to psychological insecurity, and is secondary to the primary reactions of apprehension, depression, or suspicion Early help with his emotional upsets, and a personal relationship in which he feels that his problems are understood are effective means of reassuring him and easing emotional tensions To restrict such a patient, on the other hand, is the very way to aggravate his emotional disturbance He will tend to become confirmed in his feelings of suspicion, depression, or apprehension, and his tendency to antisocial acts may be increased It would accordingly seem sensible on psychiatric grounds to substitute for long-continued custodial precautions the establishment of a personal relationship with the patient

THE HOSPITAL'S ROLE

For a comprehensive scheme to be successful the following conditions are essential integration of the hospital service with the local health authority, removal of barriers isolating the hospital from the community, an internal psychotherapeutic atmosphere in the hospital, and an enlightened and informed public opinion in the community

Integration of Hospital and Local-authority Services

This may be arranged by various administrative procedures Nottingham, for instance, has a "joint user" arrangement, under section 51 of the National Health Service Act, which enables the medical staff of the mental hospital to act also as the medical staff of the mental-health department of the local health authority[3] At York, without formal referral to the ventriculography In all four patients air encephalography showed abnormally large sulci corporis callosi, and in one the cingulate sulcus was also unusually wide and well outlined In the two tumour cases an unusual shadow was seen just to the left of the third ventricle, this shadow was half-moon shaped in the lateral position, and in the anteroposterior view was situated just to the left of the midline, being rounded medially and drawn out laterally Schechter et al thought that this latter shadow represented a dilated cisterna ambiens and confirmed this by studying the radiological appearances of this cistern in a normal brain and in the necropsy specimen of their first case after pledgets of cotton-wool soaked in radio-opaque material had been placed in the cistern

Prof G M WISHART, dean of the faculty of medicine of the University of Glasgow, died on July 18 first begin to resent the strain of looking after the old person, and before personal relationships have broken down Relief for holiday periods is arranged some months beforehand, so that the family are able to make definite arrangements to enjoy an annual rest from their responsibility of looking after the old person This is particularly important when there are young children in the household

---

[4] Castellano, F , Ruggiero, G *Acta radiol* , *Stockh* 1953, suppl 104

[5] Jones, H M , Camps, F E *Practitioner*, 1957, 178, 223

[6] Berenberg, W , Kevy, S *New Engl J Med* 1958, 258, 870

We have found that the relationship of the old person with the other member or members of the family is more important than the degree of the psychosis in determining whether admission to hospital will be necessary Once an attitude of rejection towards the old person has become firmly established in the responsible relative, no efforts on our part can alter it Help given before the attitude of rejection has become fixed, is appreciated, and the relatives are happy to continue to accept the responsibility Once the old person feels rejected he deteriorates quickly, and we accept patients who are rejected, even when the causes are mainly physical or social, because otherwise the case will rapidly become a psychiatric one

Deterioration through loneliness is common, and here we find the group atmosphere of the day occupation centre invaluable The health visitors are now reporting deaths which leave an old person living in solitude, so that arrangements may be made for them to attend the centre as a preventive measure Attendance at the centre is also useful for patients who are partially rejected by their relatives and who relapse after improvement in hospital Such patients are now introduced to the centre immediately on discharge

Because of this policy of prompt admission for a limited number of weeks, the number of geriatric admissions increased at Mapperley Hospital from 202 in 1951 to 439 in 1956 But the number of patients admitted during 1951 who were still in hospital four months after the end of the twelve months' period was 41, while the corresponding number for 1956 was 49 The geriatric inpatient wards are thus coping with many more patients without extra beds The old people are happier, and the relatives have their guilt reactions resolved, and are helped to solve their emotional conflicts We have also been able often to take preventive action through our opportunities of studying the evolution of the emotional situations and of personal relationships within the family

Where the strain on the relatives is too great, whether for physical or (more commonly) psychiatric reasons, we accept responsibility and provide a bed in the long-stay annexe Arrangements have been made for transfer of long-stay patients on an exchange basis with the geriatric wards of the general hospital or with the residential accommodation of the local-authority welfare services department This provides a method of improved classification and ensures that beds are promptly available

Schizophrenia

Patients with chronic schizophrenia and paraphrenia form a large proportion of the long-term inmates of mental hospitals They are inclined to be more uncooperative and reluctant to accept help than other psychotic patients, and their delusions may make them antisocial and resentful Compulsory short-term orders for three or seventeen days may be needed at first. Active treatment is given immediately on admission, and by the time the order ends they are usually prepared to finish their treatment as voluntary patients After discharge contact is maintained through the social worker and the aftercare clinic The patients are helped with work problems, and help is given if necessary with the home situation If they relapse or the home situation becomes too strained, readmission is arranged—again by short-term order if necessary After repeated admissions social adjustment is usually achieved If a repeated seventeen-day period proves ineffective, use of a twenty-eight day period usually is beneficial

This procedure demands much effort from the psychiatrist and social worker and high degree of cooperation from the relatives Occasionally one is just reaching the stage of feeling that a losing battle is being fought, when the attitude of the patient gradually alters and he begins to cooperate and improve Communication with schizophrenics is difficult, and on their part is effected at first through symbols Improvement is so slow as to be almost imperceptible They respond gradually and steadily to measures which maintain their self-esteem and enable them to readjust socially

The problem is more complex than of senile psychosis, and we are still trying to determine the best methods of dealing with the home situation, the work situation, and the group situation in hospital

A follow-up survey of all first admissions entering the hospital during 1954 was made to determine how many were still inpatients at the end of last year Only 9 of these 660 first admissions remained, of whom 5 were senile psychoses, 1 a case of general paralysis, 2 states of depression complicated by social and physical factors, and 1 a psychopathic state in a borderline defective No patient suffering from schizophrenia was still in hospital With these patients, too, it is important to assess that a fair balance is struck between, on the one hand, imposing too great a strain on the relatives and, on the other, ensuring that the community plays its due part in the rehabilitation of the patient

Discussion

There is a tendency to regard preoccupation with the setting in which the patient receives treatment as subsidiary to actual measures of treatment I submit that the provision of a mental health service in which the patient can be treated without disturbance of his self-respect and which preserves the essentials of the doctor-patient relationship is in itself a psychotherapeutic measure of fundamental importance The patient's self-confidence is almost always disturbed, he is emotionally upset, and needs the help of a community service even more than other patients Restriction in hospital and deprivation of civil rights undermine further his self-confidence and aggravate his emotional disturbance

Family relationships and community relationships are often seriously upset by the time a patient is brought to our notice, and a tremendous strain is imposed on a family when one member is mentally ill To treat a psychosis without dealing with such disturbed relationships is to invite subsequent relapse Prolonged removal of the patient from the family tends to make the family close its ranks and resist later attempts to restore him to their midst Many patients remain in our mental hospitals though their difficulties are no longer psychiatric but social

Often a faulty relationship with another member of the family has been one of the causes of the patient's illness, and adjustment of the attitude of this relative may be as important as the treatment of the patient These relationships in the home, at work, and in the community can be adequately dealt with only by community methods, and with a due appreciation of the need for adjustment of the attitude of the other people concerned

The mental hospital segregates people in artificial large groups It is suitable for short-term treatment and rehabilitation, but not for long-term social adjustment For this we are dependent on the family, which is accustomed to dealing with its own relationships The family group, if not disrupted and interfered with, usually

Ministry of Health, the local mental hospital is linked with the local health authority of the city At Oldham the regional hospital board and local-authority services have been integrated without incorporating the mental hospitals Good relations between medical superintendents and medical officers of health are also creating a large measure of cooperation in other areas of the country on a more informal basis

Barriers between the Hospital and the Community

The main barriers are the locked-door system and the custodial duties of the hospital The open-door principle must be established before the hospital can be accepted by the community Another barrier is certification, which segregates all those to whom it is applied from other human beings The stigma and the deprivation of civil rights cause resentment in the mind of the patient which may last many years Certification also has an adverse effect on the relationship between the patient and his relatives, his friends, and other members of the community, because it leads them to regard him as a person apart and different from themselves With modern resources in therapy, compulsion can be limited to brief periods, and arrangements made for the patient to complete his stay in hospital on a voluntary or non-statutory basis Even the voluntary formality is resented and patients' appreciate the non-statutory procedure

The Hospital's Psychotherapeutic Atmosphere

The role of the hospital in a community treatment scheme is to prepare the patient for life in the outside world again Its wards should be psychiatric rehabilitation units each with its own group atmosphere This necessitates a complete change of attitude in the staff But no true doctor-patient or nurse-patient relationship can develop so long as one party is a prisoner of the other and legally inferior to the other When the doors are open and legal disability has been removed, the staff use their personalities to deal with psychiatric crises and to help the patient to solve his problems of adjustment A happy relationship develops, and the staff (medical, nursing, and social) join with the patient to explore methods of preparing for his return to the community

Opening the doors and removal of certification are essential preliminary measures, but overcrowding must also be dealt with, so that the patient can receive adequate individual attention Community treatment makes this easier by enabling the admission units to cope with the reduced demands made on them, without having to move patients into other wards to make room for fresh admissions Accommodation for patients is not lavish and is inadequate for active rehabilitation

Many other measures, such as modernisation of ancient buildings and furnishings, more individual amenities, and the division of the patients into smaller groups, are also needed Occupational therapy is essential The patient should graduate from the occupational-therapy class to employment in the hospital departments, later to an industrial rehabilitation unit, and finally to work in the community while still living in the hospital under a "hostel" or "night hospital" scheme

Education of the Community

The attitude of the community to mental illness and to the mental hospital must be altered before there can be willing and early acceptance of psychiatric treatment by the patient The hospital and local-authority staff can lead the way, but the gap between the attitude of the public and that of the medical, nursing, and social staff should not be too great One of the first essentials in lessening the gap is an internal hospital community atmosphere in harmony with accepted standards of social behaviour, which does not offend the susceptibilities of the public when they visit the hospital A community does not accept a hospital until the patients on their return home speak with appreciation of their experience in hospital Education by lectures and other means is necessary, but is not really effective unless backed by visits to all wards and departments of the hospital where the public may see for themselves the conditions under which the patients are treated

An improved attitude to the hospital gradually leads to a more enlightened attitude to mental illness in general, and this influences the attitude of the patient to his illness He seeks treatment earlier, and is more cooperative because he is less apprehensive, and is willing to accept the help of the mental hospital as if it were a general hospital The patient is also influenced by the atmosphere of the hospital, and the staff of the admission wards believe that the most important factor in gaining the cooperation of the short-term compulsory patient is the attitude of the other patients The viewpoint of the patient, the atmosphere of the hospital, and the attitude of the community all need adjustment, but once the change has begun, each reacts beneficially on the others This enables an effective liaison to be made with employment exchanges, local employers, industrial rehabilitation units, probation departments, and all the other agencies in the community whose help the patient is likely to need Once this stage has been reached, the help given by a "league of friends" can be invaluable

WHAT CAN BE DONE AT HOME

The home visits in a community scheme of treatment may be made by social workers, by psychiatrists, or by both The visits by the psychiatrist in a service which is integrated with the mental hospital are made at the request of the mental-health department, and are in addition to domiciliary consultations at the request of the general practitioner In the Dutch scheme the first visit is made by a psychiatrist, but our experience at Nottingham suggests that there are advantages in having the first visit paid by a social worker Often the initial investigations and the early visits take much time In some cases a social worker can deal with the patient's social problems and, if need be, refer him to the outpatient department In others the psychiatrist and the social worker pay a joint visit after the preliminary investigations have been completed

TWO PRACTICAL EXAMPLES

Senile psychosis and schizophrenia are two illnesses which fill many hospital beds and cause overcrowding of hospital wards To illustrate the use of community treatment methods as an alternative to long-term or permanent inpatient stay I shall describe the procedures we use with these two psychoses at Nottingham

Senile Psychosis

When a patient aged 65 or over is reported to the mental health department of the local health authority, a domiciliary visit is arranged by a psychiatrist and a social worker They assess the home situation and decide whether the problem is primarily psychiatric, physical, or social If it is psychiatric, they decide whether the patient can be cared for in the community or needs admission to hospital If community care is chosen, the social worker gets in touch with relatives, arranges for home help, informs health visitors or the welfare services department, and takes all other necessary action Attendance at the day occupational centre is arranged when this is thought appropriate and helpful

If admission to hospital is necessary, it is explained to the patient and to the relatives that admission is for four weeks only The cooperation of the old person is obtained, and reassurance is given that there is no question of his being "put away" The relatives are assured that further help will be forthcoming when needed and that no undue burden will be placed on them, but that they must play their part and continue to accept responsibility for the old person In these general discussions with the relatives and the old person we try to show them the situation as a shared problem, to the solution of which all, including the psychiatrist and the social worker, must contribute Short admissions are now being arranged at an earlier stage of the illness, when the relatives first begin to resent the strain of looking after the old person, and before personal relationships have broken down Relief for holiday periods is arranged some months beforehand, so that the family are able to make definite arrangements to enjoy an annual rest from their responsibility of looking after the old person This is particularly important when there are young children in the household

We have found that the relationship of the old person with the other member or members of the family is more important than the degree of the psychosis in determining whether admission to hospital will be necessary Once an attitude of rejection towards the old person has become firmly established in the responsible relative, no efforts on our part can alter it. Help given before the attitude of rejection has become fixed, is appreciated, and the relatives are happy to continue to accept the responsibility Once the old person feels rejected he deteriorates quickly, and we accept patients who are rejected, even when the causes are mainly physical or social, because otherwise the case will rapidly become a psychiatric one

Deterioration through loneliness is common, and here we find the group atmosphere of the day occupation centre invaluable The health visitors are now reporting deaths which leave an old person living in solitude, so that arrangements may be made for them to attend the centre as a preventive measure Attendance at the centre is also useful for patients who are partially rejected by their relatives and who relapse after improvement in hospital Such patients are now introduced to the centre immediately on discharge

Because of this policy of prompt admission for a limited number of weeks, the number of geriatric admissions increased at Mapperley Hospital from 202 in 1951 to 439 in 1956 But the number of patients admitted during 1951 who were still in hospital four months after the end of the twelve months' period was 41, while the corresponding number for 1956 was 49 The geriatric inpatient wards are thus coping with many more patients without extra beds The old people are happier, and the relatives have their guilt reactions resolved, and are helped to solve their emotional conflicts We have also been able often to take preventive action through our opportunities of studying the evolution of the emotional situations and of personal relationships within the family

Where the strain on the relatives is too great, whether for physical or (more commonly) psychiatric reasons, we accept responsibility and provide a bed in the long-stay annexe Arrangements have been made for transfer of long-stay patients on an exchange basis with the geriatric wards of the general hospital or with the residential accommodation of the local-authority welfare services department This provides a method of improved classification and ensures that beds are promptly available

Schizophrenia

Patients with chronic schizophrenia and paraphrenia form a large proportion of the long-term inmates of mental hospitals They are inclined to be more uncooperative and reluctant to accept help than other psychotic patients, and their delusions may make them antisocial and resentful Compulsory short-term orders for three or seventeen days may be needed at first. Active treatment is given immediately on admission, and by the time the order ends they are usually prepared to finish their treatment as voluntary patients After discharge contact is maintained through the social worker and the aftercare clinic The patients are helped with work problems, and help is given if necessary with the home situation If they relapse or the home situation becomes too strained, readmission is arranged—again by short-term order if necessary After repeated admissions social adjustment is usually achieved If a repeated seventeen-day period proves ineffective, use of a twenty-eight day period usually is beneficial

This procedure demands much effort from the psychiatrist and social worker and high degree of cooperation from the relatives Occasionally one is just reaching the stage of feeling that a losing battle is being fought, when the attitude of the patient gradually alters and he begins to cooperate and improve. Communication with schizophrenics is difficult, and on their part is effected at first through symbols Improvement is so slow as to be almost imperceptible They respond gradually and steadily to measures which maintain their self-esteem and enable them to readjust socially

The problem is more complex than of senile psychosis, and we are still trying to determine the best methods of dealing with the home situation, the work situation, and the group situation in hospital

A follow-up survey of all first admissions entering the hospital during 1954 was made to determine how many were still inpatients at the end of last year Only 9 of these 660 first admissions remained, of whom 5 were senile psychoses, 1 a case of general paralysis, 2 states of depression complicated by social and physical factors, and 1 a psychopathic state in a borderline defective No patient suffering from schizophrenia was still in hospital With these patients, too, it is important to assess that a fair balance is struck between, on the one hand, imposing too great a strain on the relatives and, on the other, ensuring that the community plays its due part in the rehabilitation of the patient

Discussion

There is a tendency to regard preoccupation with the setting in which the patient receives treatment as subsidiary to actual measures of treatment I submit that the provision of a mental health service in which the patient can be treated without disturbance of his self-respect and which preserves the essentials of the doctor-patient relationship is in itself a psychotherapeutic measure of fundamental importance The patient's self-confidence is almost always disturbed, he is emotionally upset, and needs the help of a community service even more than other patients Restriction in hospital and deprivation of civil rights undermine further his self-confidence and aggravate his emotional disturbance

Family relationships and community relationships are often seriously upset by the time a patient is brought to our notice, and a tremendous strain is imposed on a family when one member is mentally ill To treat a psychosis without dealing with such disturbed relationships is to invite subsequent relapse Prolonged removal of the patient from the family tends to make the family close its ranks and resist later attempts to restore him to their midst Many patients remain in our mental hospitals though their difficulties are no longer psychiatric but social

Often a faulty relationship with another member of the family has been one of the causes of the patient's illness, and adjustment of the attitude of this relative may be as important as the treatment of the patient These relationships in the home, at work, and in the community can be adequately dealt with only by community methods, and with a due appreciation of the need for adjustment of the attitude of the other people concerned

The mental hospital segregates people in artificial large groups It is suitable for short-term treatment and rehabilitation, but not for long-term social adjustment. For this we are dependent on the family, which is accustomed to dealing with its own relationships The family group, if not disrupted and interfered with, usually accepts responsibility for solving its own problems This attitude, if helped and directed into psychotherapeutic channels, can be a powerful rehabilitating factor We should treat the family as the unit—not the patient in isolation

Community treatment averts the development of antisocial attitudes and the overlay of aggression which are produced by compulsion and restrictions, and thus leaves the patients free to deal with their problems of social adjustment Their psychotic symptoms, if fully established, are not eradicated, but they cease to be the major and dominating factor in the patient's existence Compulsory long-term hospital care tends to perpetuate the dominance of the psychosis, whereas the more flexible regime of community treatment encourages the patient's natural tendency to social readjustment and helps him to remain in the community despite the handicap of chronic psychosis

One definite advantage of community treatment is that by means of domiciliary visits psychiatric illness is treated at an even earlier stage than is possible with the outpatient clinic In an integrated mental health service the home and health visitors recognise psychiatric situations before serious symptoms have developed Potential stages of a serious breakdown can be treated, and prophylactic measures started in a way which is impossible without a community service In taking these early steps it is essential to inform the patient's general practitioner, so that he remains a member of the team In Nottingham the system has tightened the links between the mental health service and the general practitioners, who often now refer patients for attendance at the day centre, and for other prophylactic measures, instead of merely referring them for admission

To sum up, community treatment not only makes possible continuity of care for all forms of psychiatric illness but by its beneficial influence on public opinion persuades patients and their relatives to come spontaneously to the mental health department for help and advice, and to accept the mental hospital, like the general hospital, as a place where the patient goes to speed his rehabilitation

Evaluation of the benefit offered to the psychiatric patient by community treatment must await scientific appraisal, but its advantages are already sufficiently clear to justify a critical attitude towards rigid measures of long-term hospital treatment The possible methods of providing this treatment should be given a practical trial and the results of these experimental schemes studied carefully, so that we may, in due course, judge which is best for the patient

INTERNATIONAL FEDERATION OF SURGICAL COLLEGES

THIS Federation was formally inaugurated in Stockholm on July 4 Its aims are

The establishment and maintenance of close relations among approved surgical colleges and kindred institutions

The encouragement of the maintenance of high standards of education, training, and research in surgery and its allied sciences

At the meeting in Stockholm Sir Harry Platt was elected president for the next three years, and Dr I S Ravdin (U S A) and Dr E Dahl-Iversen (Denmark) were elected vice-presidents The other members of the executive committee in the first instance will be representatives from Holland, France, Sweden, Norway, Belgium, and Australasia The member-institutions are

Academy of Surgery of Paris, American College of Surgeons, Belgian Surgical Society, College of Physicians, Surgeons, and Gynæcologists of South Africa, Danish College of University Surgeons, Dutch Association of Surgeons, Italian Surgical Society, Norwegian Surgical Association, Royal Australasian College of Surgeons, Royal College of Physicians and Surgeons of Canada, Royal College of Surgeons of Edinburgh, Royal College of Surgeons of England, Royal College of Surgeons in Ireland, Royal Faculty of Physicians and Surgeons of Glasgow, Swedish Surgical Society

The secretary of the Federation is Mr Kennedy Cassels, Royal College of Surgeons of England, Lincoln's Inn Fields, London, W C 2

Public Health

No More Fluoride at Andover

IN 1955 Andover Borough Council unanimously accepted their public-health committee's recommendation that the town should be one of the four areas to take part in the Ministry of Health's scheme to study the effect of adding sodium fluoride to water-supplies as a means of preventing dental decay among children Fluoridation of the town's water accordingly began on July 17, 1956 The proposal aroused local opposition, and an anti-fluoride association was formed which collected funds from ratepayers and ultimately brought an action against the council on the ground that they had acted beyond their powers in introducing fluoridation

In the meantime, at the recent borough election, most of the councillors who were in favour of fluoridation lost their seats, and the newly elected council on July 1 adopted their public-health committee's recommendation to stop the fluoridation of the town's water-supply without delay This decision was put into effect on July 2 The legal action has been adjourned *sine die*

The First Quarter

Reports on the first quarter of this year in England and Wales,[1] Scotland,[2] and Eire[3] include the following figures (the figures for the corresponding quarter in 1957 are included for comparison)

—	England and Wales		Scotland		Eire	
	1958	1957	1958	1957	1958	1957
Birth rate (per 1000 population)	17 2	16 6	19 7	19 5	20 1	20 4
Death rate (per 1000 population)	14 8	12 2	14 6	12 7	14 1	13 4
Infant-mortality rate (per 1000 live births)	25 1	25 2	32	32	44	38
Tuberculosis death rate (per 100,000 population)	14 2	11 7	18	17	24	25

In England and Wales in 1957, according to provisional figures, 6715 deaths from influenza were registered, compared with 2626 in 1956 and 2983 in 1955 Deaths from acute poliomyelitis numbered 225 in 1957—111 more than in 1956, but 16 less than in 1955 There were 2 deaths from smallpox last year—the first in this country since 1953 The infant-mortality in England and Wales as a whole was 23 1 per 1000 live births in 1957, compared with 24 9 in 1955, the corresponding rates for Wales alone were 28 4 and 31 4

Congresses

STRESS AND MENTAL ILLNESS

In an intense and interesting conference in Oxford last week, some 40 distinguished scientists, predominantly psychiatrists, psychologists, and physiologists, brought together by the Mental Health Research Fund, tackled the subject of "stress" and its action on man's health, particularly the health of his mind They set out to clarify the mass of facts that have sprung in recent years from the growing attack on the questions of how and why the animal reacts to the pressure of its environment in such a bewildering variety of ways People trained in several disciplines, precise and less precise, and often talking therefore in conflicting terms, have contributed to knowledge of the phenomena that this reaction can generate, and the meeting gave prominent thinkers in this branch of biology the chance to illuminate by close contact, often outside the conference room, the difficulties of effectively communicating to one another the observations they have made and the significance they put upon them. Their formal deliberations suggested that it is not yet possible to sketch with confidence an embracing and unifying picture that will include the whole scene. But the gaps that separate the more sharply defined schools of thought—the physiologically minded and those who think in psychological terms, for instance—were not so wide as they at first sight seemed, and some promising bridge-building materials became apparent.

In the report that follows, we can note only a few of the contributions that the conference heard, and the balance between the physiological, the psychiatric, the psychological, the psychosocial must be ill struck, but it is an immediate record of a notable attempt to sum up progress in a subject that may at present defy summing up We hope that the Fund will publish the proceedings in greater detail, prefaced or concluded perhaps by a further analysis and judgment.

WHAT IS STRESS?

In its daunting venture, the conference was fortunate in having as its leader Sir **Geoffrey Vickers**, chairman of the research committee of the Mental Health Research Fund, who was more than equal to the task of giving profitable direction to swiftly changing lines of thought. A prime difficulty, never fully resolved, was to decide what meaning or meanings to attach to the word "stress" Dr **Derek Richter** had prepared for the conference's consideration a concise memorandum on the current usage of this term by different scientists—physicists, biologists, physiologists, psychologists—and ranging from the physicist's precision of dynes per sq cm to the psychologist's "anxiety, tension, or a defensive behavioural response" This helpful document was never formally discussed such a discussion might have served as a clarifying preliminary debate. As it was, everyone understandably adhered to his own notions, without much explanatory definition, and in the early exchanges this was a source of difficulty Sir Geoffrey promptly recognised this nettle and seized it firmly by issuing, on the second morning of the conference, a note on the meanings attached to "stress" during the first day's discussions In this he said

"We require a word to cover all those felt needs which evoke purposeful activity If this be 'stress', then, as Professor Selye says, only death can relieve it To avoid so wide an application, I will use the word 'challenge' to cover both the need and the signal which evokes action to meet it.

"The course of response to these challenges may pass through several stages

(i) The organism can meet the need
(ii) The organism can meet the need but only for a period which may not be sufficient.
(iii) The organism cannot meet the need without abandoning, at least for the time being, the effort to pursue or evade some other relationship
(iv) The organism cannot meet the need at all

"If these stages occur successively the state of the organism will change along four dimensions which are not exactly correlated and all these changes may, in current usage, be attributed to 'stress'

(i) It will change physiologically These changes will depend partly on the energy requirements of the response and partly on its emotional accompaniment. They may begin at stage (i) and often reach their peak in stage (ii) unless they are later complicated by the indirect effect of subsequent stages
(ii) It will change emotionally Anxiety may arise irrationally at stage (i) or rationally at stage (ii) The whole gamut of emotional changes may appear in the course of stages (iii) and (iv)
(iii) It will change behaviourally At the end of stage (ii) its behaviour towards some or all of its other goals will change. At stage (iv) or earlier it will give up its purposeful activity towards the relation which is being defeated
(iv) It will change structurally From the end of stage (ii) it becomes differently structured, as it abandons or modifies one after another of its governing relations"

And he concluded

"To clarify our discussion, I make the following suggestions.

(1) We are concerned with four separate objects of attention, for which we need separate words It is unfortunate that three of these are themselves fourfold.

(i) Four types of (more or less) observable change,
(ii) the situations which cause these changes,
(iii) the processes by which these changes take place,
(iv) the behaviours which accompany these processes

(2) The simplest way, consistent with existing usage, in which we can mark these distinctions, when we want to be precise, is, I suggest, to refer to them as 'stress-change', 'stress-situation', 'stress-process', and 'stress-behaviour'

The terms 'stressor' and 'stress-response' have such strong physiological connotations that they are best reserved for that field, but they would be included by the wider terms 'stress-situation', 'stress-change', and 'stress-behaviour'

(3) Though the four types of change—physiological, emotional, behavioural, and structural—are intimately related, there is clearly not a one-to-one correspondence between them. We should not assume that they are different aspects of the same 'thing', except in so far as we know them to be exactly correlated

(4) The only valid general use of the word 'stress' at present is adjectival It connotes a degree of challenge sufficient to evoke the kind of change or behaviour which interests the particular observer Its meaning therefore depends not only on the 'dimension' in which he is interested but also on the threshold above which appear the kind of phenomena which he finds interesting"

The conference did not achieve a better clarification of terminology than this

MATCHING OF PATTERNS

In his opening remarks, Sir **Geoffrey Vickers** pointed out that disorganisation—or inability to function at one's normal level—might, in fact, be defensive reorganisation exercising a protective role As Field-Marshal Lord Wavell put it, stupidity in generals should never excite surprise, since they were of the few tough enough to be generals at all, their essential qualification being their ability to function at some level in conditions of stress which would cause less stable organisms to break down

The stressful situation which concerned the psychiatrist was produced not by events but by the organism's interpretation of events in relation to itself This in turn was a function of the way in which the individual personality was organised. and any conceptual model of this must include the organisation of experience There accepts responsibility for solving its own problems This attitude, if helped and directed into psychotherapeutic channels, can be a powerful rehabilitating factor We should treat the family as the unit—not the patient in isolation

Community treatment averts the development of antisocial attitudes and the overlay of aggression which are produced by compulsion and restrictions, and thus leaves the patients free to deal with their problems of social adjustment Their psychotic symptoms, if fully established, are not eradicated, but they cease to be the major and dominating factor in the patient's existence Compulsory long-term hospital care tends to perpetuate the dominance of the psychosis, whereas the more flexible regime of community treatment encourages the patient's natural tendency to social readjustment and helps him to remain in the community despite the handicap of chronic psychosis

One definite advantage of community treatment is that by means of domiciliary visits psychiatric illness is treated at an even earlier stage than is possible with the outpatient clinic In an integrated mental health service the home and health visitors recognise psychiatric situations before serious symptoms have developed Potential stages of a serious breakdown can be treated, and prophylactic measures started in a way which is impossible without a community service In taking these early steps it is essential to inform the patient's general practitioner, so that he remains a member of the team In Nottingham the system has tightened the links between the mental health service and the general practitioners, who often now refer patients for attendance at the day centre, and for other prophylactic measures, instead of merely referring them for admission

To sum up, community treatment not only makes possible continuity of care for all forms of psychiatric illness but by its beneficial influence on public opinion persuades patients and their relatives to come spontaneously to the mental health department for help and advice, and to accept the mental hospital, like the general hospital, as a place where the patient goes to speed his rehabilitation

Evaluation of the benefit offered to the psychiatric patient by community treatment must await scientific appraisal, but its advantages are already sufficiently clear to justify a critical attitude towards rigid measures of long-term hospital treatment The possible methods of providing this treatment should be given a practical trial and the results of these experimental schemes studied carefully, so that we may, in due course, judge which is best for the patient

Fuller (Bar Harbor, Maine) was particularly interested by the high death-rate in the animals exposed to only a short stress. Could it be that this was the little pebble that started the organism on the non-conformist road, from which it was very hard to turn back?

PRISONERS OF WAR

In the matter of increased mortality in organisms exposed to some form of severe stress, Professor Wolff presented figures derived from a recently completed study of United States prisoners of war. In the late war, 94,000 United States prisoners were taken in Europe and were imprisoned for about ten months. Less than 1% died before liberation. In the Pacific theatre 25,000 Americans became prisoners: they were in prison about four times as long as those captured in Europe and suffered far more threats, abuse, and humiliation. More than a third died before liberation. In the six years after liberation the number of deaths in the Pacific prisoners was more than twice the expected incidence in a similar group not exposed to the hazards of prison camps. The mortality-rate was three times greater in the Pacific than in the European prisoners. Deaths from heart-disease were twice as common, from cancer twice, from gastro-intestinal diseases four times, from suicide twice, from accidents three times, and from pulmonary tuberculosis nine times as common.

STRESS AND EXPERIMENTAL PHYSIOLOGY

To those who found it hard to get a foothold among the psychological and psychiatric concepts of stress and responses to it, Prof. Hans Selye (Montreal) offered the firmer ground of facts gathered in his long study of experimental stress. Inflammation in the limb of a rat caused by the local injection of formalin could be modified by pretreatment with hormones: corticotrophin (A.C.T.H.) inhibited the inflammatory response and somatotrophin (S.T.H.) enhanced it. The intraperitoneal or intravenous injection of egg-white induced an anaphylactic reaction in the rat, and this could be inhibited by stress, but not in the adrenalectomised animal. The changes of periarteritis nodosa could be produced in the rat by administering an anticortisone hormone, such as deoxycortone. Partial ligature of a mesenteric vessel prevented these changes developing in the distribution of that vessel, indicating that the blood-vessels of the hormone-conditioned animal could be damaged by blood-pressures which were of no account in the untreated animal. Cortisone prevented the onset of bone lathyrism in rats fed on a diet that would induce the disease in untreated animals, and conversely S.T.H. would promote severe bone changes in rats eating a diet in which there were only small amounts of lathyrus, amounts that were not previously harmful.

What Professor Selye described as the most important outcome of twenty years' work was the experimental production of cardiac necrosis in rats exposed to corticoid hormones plus immobilisation. A special staining technique identified the areas of muscle susceptible to necrosis by demonstrating early prenecrotic degenerative changes. Potassium and magnesium ions had been shown to prevent these changes. Some aspects of this work have lately been described[1] in these columns.

Professor Selye owned, however, that only a very small part of the reaction to stress was mediated by hormones and by disturbances in the balance of hormone pairs, for, in hypophysectomised animals, the adaption syndrome proceeded much as in the intact animal.

As a supplement to Professor Selye's contribution, Prof. G. W. Harris (London) discussed a possible link between the nervous system and the endocrine glands. The stimulation of neural structures above the hypophysis—in the hypothalamus—evoked changes in target organs similar to those recorded by Selye. The portal system in the pituitary blood-supply suggested that this effect was transmitted by a humoral mechanism.

THE BODILY STRESS RESPONSE

Dr Hudson Hoagland (Shrewsbury, Mass.) described work on urinary metabolites done at the Worcester Foundation for Experimental Biology. The excretion of adrenaline and noradrenaline was measured in ice-hockey players, boxers, and psychiatric patients.

A group of Olympic boxers all had a high adrenaline output (about five times normal) before a fight, the noradrenaline was not raised, except in 2 men who engaged in vigorous shadow boxing before a fight. After the fight, noradrenaline excretion was very high and the adrenaline figures remained high.

Measurements in the Boston Bruins, a tough ice-hockey team, showed a similar pattern. In the 4 players actively skating, noradrenaline output was five to ten times higher after a game, while adrenaline excretion was relatively low. In 2 players "benched" for injuries, adrenaline figures went up while they were watching, and a player who became involved in a fight excreted very large quantities of noradrenaline.

	Noradrenaline (µg per 100 mg	Adrenaline creatinine)
Active players		
Pre-game	2·7	0·36
Post-game	15·3	0·05
Non-players		
Pre-game	2·2	0·23
Post-game	3·3	0·75
Fighting player		
Pre-game	3·5	
Post-game	29·3	

The Bruins coach, evidently a phlegmatic fellow, never showed much response, as judged by excretion of adrenaline and noradrenaline, except as the result of a particularly arduous game with the Montreal team (a finding of which Professor Selye expressed approval).

Anxiety, it could be concluded, was associated with increased adrenaline output, and exercise with a rise in noradrenaline excretion. Similarly, in the psychiatric patients, the active aggressive type was the one who usually excreted more noradrenaline.

Dr John I. Lacey (Yellow Springs, Ohio) said that in the individual the physiological indications of the imposed load were unevenly distributed. Each individual might react violently in one particular way, such as change in skin blood-flow or systolic blood-pressure, and Dr Lacey pictured a continuum between the random response at one extreme and the stereotyped response at the other.

DISTURBED BEHAVIOUR IN CHILDREN

Describing research on encopresis in outpatients at the children's department of the Maudsley Hospital, Dr E. J. Anthony (London) referred to three types of toilet training (coercive, normal cooperative, and neglectful) and to three main types of soiling disturbance—continuous (from infancy), retentive (with overflow), and discontinuous (after a period of bowel continence). In the group of children studied 75% of retentive encopresis and 63% of discontinuous encopresis was associated with a coercive form of training. On the other hand in 68% of continuous encopresis the training was neglectful. 80% of neglectfully trained children showed a weak 'aversion' reaction, as judged by a perceptual battery, was a need for the better integration of the concepts of the various facets of man, his physiology, the way he perceives and learns, his mental energy Some recent developments already made for better integration The electroencephalograph might provide a physiological measure of some aspects of personality and personal integration, and had suggested to Dr Grey Walter a physiological theory of learning

---

[1] Selye H. *Lancet*, 1958, i, 1351

A recurring idea was that of matching with a pattern The raw material of experience was not the whole of the "blooming, buzzing confusion" which surrounded us but a selection of the regularities which we could detect, and these in turn provided the categories for the classification of further experience Conditioning depended on recognising regular relations between recurrent events in such categories Judgments of value were linked to situations recognised by their correspondence to some pattern previously experienced Expectation, then, played a large part in the organisation and disorganisation of personality, for what we knew consciously as expectation was only the exposed part of an iceberg that floated very low in the water

Conflict was not necessarily noxious in itself its outcome depended on the organisation of a given individual and his vulnerability to a particular form of stress Today the world was full of energy waiting to be borrowed, and the weakest signal might release gigantic force, for "the development of our mental powers has endowed us with so alarming a capacity for organisation —and disorganisation"

"PSYCHOSOMATIC?"

Prof Harold G Wolff (New York) distinguished between direct-acting stimuli (strong physical assaults, such as heat and cold) and those of lower intensity with an indirect action and the capacity to act as signals to the organism This division of stimuli corresponded closely to Professor Selye's non-conditional and conditional stresses Professor Wolff described an investigation into the medical history of 3500 people living in the United States, including 1700 semi-skilled women, 1500 skilled men, and smaller groups of Chinese graduates, Hungarian refugees, and recent American graduates preparing to be executives Of all the recorded illnesses in these 3500 people, two-thirds were concentrated in a quarter of the group Clusters of illness could be identified in many individuals, and the great majority of clusters occurred at times when the individual perceived his life situation to be unsatisfying or over-demanding, at times of threat to security or failure to satisfy important personal needs Statistical analysis supported the conclusion that illness-episode rate was greater at times of unsatisfactory life situation Professor Wolff's findings had made him uneasy about the validity of labelling certain illnesses "psychosomatic" There was no difference, it seemed, between peptic ulcer, gout, or breast cancer in their relationship to the patient's stress The majority of symptomatic illness (medical, surgical, or psychiatric) arose in, or might be remarkably influenced by, environmental circumstances which the individual conceived as threatening It might be that the life of the highly stressed person was telescoped in a way that brought him at an earlier age into the period of life at which malignant disease was commoner

DISORGANISATION OF BEHAVIOUR IN ANIMALS

Dr R A Hinde (Cambridge) discussed problems arising in animals beset by conflicting tendencies in natural or near-natural conditions In Nature higher animals were rarely single-minded the territorial song bird would attack conspecific animals which it encountered on its own territory, but it would flee from those it met outside that limit, encounters at the border of a bird's territory would evoke a confused response Conflicting tendencies might lead to the inhibition of all but one response or group of responses thus, a cat would not feed at a site where it had experienced alarm, even though it was starving The distinction between redirection activity and displacement activity in animals is very relevant in the attempt to relate animal to human behaviour In redirection activity an appropriate response may be directed to an inappropriate object both sexual and aggressive behaviour may be evoked by its mate in the male black-headed gull, and the mate may redirect the aggression to some passer-by In displacement activity, the action of the animal is apparently inappropriate starlings may suddenly preen their feathers during a fight, or they may show vigorous foraging movements before copulation Such displacement activity had been attributed to an "excess of drive", to "sparking over" from one centre of activity to another, but Dr Hinde was dissatisfied with this hypothesis The present trend was to look for common causal factors within the normal context In the deprived animal some link necessary for the chain of normal behaviour was missing, and the animal might respond to a stimulus that was usually inadequate Such a response might in fact be usefully adaptive, but it could result in bizarre stereotyped behaviour Two chaffinches deprived of material for nest-making plucked their breasts bare to feather their own nest In later nesting seasons, they continued to strip themselves of feathers, even though there was abundant nesting material available

Prof Martin Roth (Newcastle upon Tyne) reflected on the possible selective advantages of inappropriate displacement activity or repetitive activity Was the unresponsiveness of schizophrenics exposed to hard conditions in any way the outcome of a selective process?

Prof Howard S Liddell (New York) has for many years been investigating, at the Behaviour Farm Laboratory of Cornell University, the establishment of conditioned reflexes in animals and the generation thereby of experimental neurosis An observation which attracted much interest was that concerning differences in mortality between goats conditioned ("trained") during a period of separation from their mother and those trained while the normal relationship with the mother continued Of 10 young goats trained for a very short time (four to fourteen hours) without their mother, 2 died quickly, and hæmorrhages were found in the adrenal cortex at necropsy 4 out of 5 twin pairs trained without their mother died in their first year of life, but only 1 out of 5 pairs trained with their mother died in that time In Professor Liddell's experience, separation of the kid from its mother five minutes after birth could disrupt the maternal relationship, which could never then be established normally even though the period of separation was only a few hours Professor Liddell believed that all conditioning was neurotogenic—a view that was questioned by some members of the conference Prof G R Hargreaves (Leeds) remarked that all Professor Liddell's animals were much constrained passive recipients of noxious stimulants It might not be the conditioning that produced the neurosis Dr J chemical was not available. The mortality was reduced from 24.5% to 7.5%, and the duration of fever and of stay in hospital by about half. Haemorrhage and perforation remain serious complications, and in the gravely ill fluid and electrolyte balance is important. Dr. Vaizey reported the emergence of chloramphenicol-resistant strains of *Salmonella typhi*.

Duodenal Ulcer

Dr. A. A. Khan reported that in Africans in Kenya duodenal ulcer is on the increase. It affects all income, social and educational groups. It is a disease of young and middle-aged Africans, aged 18-45—the age-group that is likely to suffer the greatest conflicts, fears, and frustrations. As more Africans become urbanized, the incidence of duodenal ulcer may be expected to increase correspondingly.

Pulmonary Amoebiasis

Dr. L. B. Nevill drew attention to amoebiasis in its more severe and virulent forms in Nakuru and district. Of seven cases of pulmonary amoebiasis, in five the lung was infected via the liver and in two the infection was blood-borne. In all cases treatment with emetine and chloroquine was successful.

A Malabsorption Syndrome

Dr. A. G. Shaper said that steatorrhoea is excessively rare in Africans. He described one case, and referred to a second under investigation.

A 21-year-old Muganda presented with the "adult kwashiorkor" picture and investigation confirmed the presence of steatorrhoea and diffuse pancreatic calcification. At necropsy he was found to have pancreatic lithiasis, a fatty liver, and secondary atrophic changes in the small bowel, testes, and adrenals.

Pancreatitis was judged to play no part in the aetiology of this syndrome. Dr. Shaper holds that diffuse pancreatic lithiasis is distinct from the parenchymal calcification of chronic pancreatitis. The term "adult kwashiorkor" almost certainly embraces conditions of widely different aetiology and should be used with caution, if at all.

Drug Allergy and Contact Dermatitis

Dr. A. Henderson-Begg drew attention to the importance of history-taking in this type of case: patients who state categorically that they are taking no drugs or medicines may be found on specific questioning to be taking any of a wide variety of proprietary preparations, many of which (such as tonics, douches, contraceptives, and local anaesthetics) may not be regarded as medicines. In view of the large number of children today receiving sensitizing drugs, the incidence of drug allergy may be far higher in the rising generation. Dr. Henderson-Begg described four cases—two of aspirin allergy, one of phenolphthalein allergy, and one of contact dermatitis of the forearms due to paraphenylenediamine sensitization, with cross-sensitization to procaine.

Occasional Survey

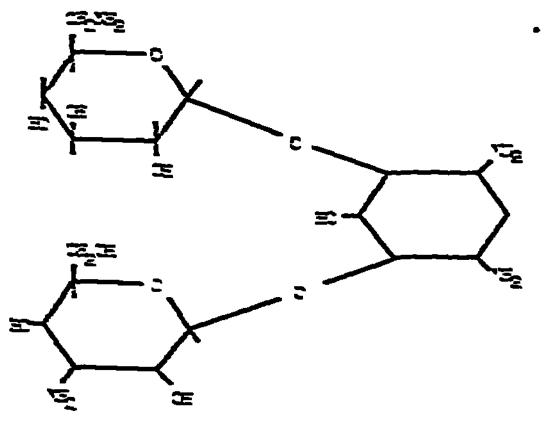
KANAMYCIN

MAXWELL FINLAND
M.D.

From the Thorndike Memorial Laboratory, Second and Fourth (Harvard) Medical Services, Boston City Hospital, and Department of Medicine, Harvard Medical School, Boston, Mass., U.S.A.

The increasing difficulties that are being encountered in the management of resistant staphylococcal and urinary tract infections and in the retreatment of cases of tuberculosis have stimulated interest in the development of new antibiotics that might prove effective in the treatment of such cases. Kanamycin, an antibiotic related to neomycin but exhibiting considerably less toxicity, is active against most of the causative organisms in such cases and should, therefore, be of interest. A conference on the basic and clinical research of this new antibiotic was held at the New York Academy of Sciences on July 10 and 11, and this paper represents a summary of the data presented at that conference.

The conference was concerned with the soluble, basic antibiotic, kanamycin, discovered by Umezawa and his co-workers in the fermentation products of *Streptomyces kanamyceticus*. Chemically this antibiotic was shown to be closely related in its structure to neomycin and to have some features in common with streptomycin but to be clearly distinct from both; it consists of 2 amino sugars linked glycosidically to 2-deoxystreptamine. The chemical structure and physical properties of kanamycin have been almost fully elucidated and, as the sulphate, it is remarkably stable, readily soluble, and suitable for intramuscular use.



The structural formula (see figure) was presented by Cron as the one that best fits all the known data.

EXPERIMENTAL EVIDENCE

In vitro, kanamycin was shown to be highly or moderately active against many common pathogenic aerobic gram-positive and gram-negative bacteria and mycobacteria; but some pneumococci, most streptococci, and pseudomonas were found to be moderately or highly resistant, and anaerobic organisms, yeasts, and fungi were nearly all highly resistant. Of immediate interest is its activity against pathogenic staphylococci irrespective of their resistance to other antibiotics now in common use. Its activity parallels very closely that of neomycin and of paromomycin. Resistance to kanamycin can be readily induced in staphylococci and in *Escherichia coli*, and this is accompanied by complete cross-resistance to neomycin and paromomycin and partial cross-resistance to streptomycin and certain other related antibiotics, but no cross-resistance with any of the other antibiotics that are generally available. Fresh isolates of various bacteria also show this cross-resistance among kanamycin, neomycin, and paromomycin, but streptomycin-resistant strains do not show cross-resistance to kanamycin and to the other related antibiotics. In the tubercle bacillus there appears to be complete cross-resistance between kanamycin and neomycin and one-way cross-resistance from viomycin to kanamycin.

In the usual laboratory animals kanamycin has shown relatively low acute toxicity. Subacute and chronic administration revealed toxicity that was similar to, but slightly less than, that of streptomycin and dihydrostreptomycin and much less than that of neomycin. In particular, the adverse vestibular and auditory effects occur in experimental animals after larger doses and after but 76% of those coercively trained reacted strongly A group of children with sleep disturbances were compared with neurotic controls to assess the influence of various factors suggested as causes of sleep disturbance Significant differences were found which pointed to sleeping in the parental bedroom, separation trauma, and phobia in the mother as important influences

PSYCHOSOCIAL REMEDIES

In the discussion on the prevention and treatment by psychosocial means of psychiatric reactions to stress, Dr J D **SUTHERLAND** (London) expressed doubts about present-day psychiatric institutions Too many, he felt, still isolated and repressed the patient. They must become open systems having much more communication with society Dr Sutherland's colleague at the Tavistock Clinic, Mr Eric Trist, had been investigating the sociotechnical system, the complex matching of social and technical factors in the individual's working environment If the matching was inadequate, tension resulted, and a thorough analysis of the circumstances could often indicate the right remedy

APPRAISALS

Dr **DENIS HILL** (London), in a skilful review of the first three days of the conference, drew together some of the threads He recalled how rarely the word "stress" had been used until comparatively recent years Freud had not used it, Darwin was the one who came nearest to it in his definition of the struggle for existence He did not think that the stressor could be defined it owed its stressing quality to the nature of the individual, and it was the meaning of experience that mattered This importance of the meaning of a stimulus to the organism stimulated recurred throughout the discussions Dr Hill had found Dr Hinde's views on animal behaviour to be in line with clinical experience He pointed specially to Dr Hoagland's finding that the better the individual's performance at a task the less his steroid output and, in one sense, the less the stress he sustained; and to Professor Selye's demonstration that the duration of stress determined its effects Dr Hill attached importance also to Dr Lacey's view that the autonomic nervous system was *not just an atavistic instrument, not just an efferent* system, but one which had important feedback functions The conference, he thought, should direct its attention not to effects but to the stress process itself And in that inquiry Dr Hinde's guidance on the features of displacement behaviour in birds might be relevant to the study of tics and compulsions in man

Action in some form relieved tension man sought to escape from the prison of his social environment Any prolongation of stress, any delay in the adaptive process was damaging to mental and physical health, and could even, it seemed, shorten life It could also be argued that a neurosis was therefore preferable to continued stress

Prof R W **GERARD** (Ann Arbor) proposed a transliteration from the psychosocial to the neurophysiological He pictured the build-up in the nervous system of stimuli generated by maintained uncertainty, leading to reverberation and the continued passage of messages round looped systems If such stimuli went round long enough they became permanent Such a process could contribute to learning Hamsters who had found their way through a maze would remember and benefit from their experience only if they were given time to do so If their brains were stunned electrically immediately after the animals had explored the maze, they did not remember When the reverberating disturbance was sufficiently great the stimulus could spread to the hypothalamus An increasing number of cells became involved and finally the whole neurone assembly was committed, so that no cell reserves remained At this stage, in Dr Gerard's hypothesis, non-adaptive stereotyped behaviour predominated

ASSOCIATION OF PHYSICIANS OF EAST AFRICA

THE annual conference was held in Nairobi, under the presidency of Dr A D **CHARTERS**, on June 26-28

Tuberculous Pericarditis

Dr P P **TURNER** said that tuberculous pericarditis is common in East Africa and is commonly fatal There is no specific physical sign, other than a friction rub Culture of fluid from the pericardial sac is positive in about a third of the cases. Removal of fluid is often essential in cardiac tamponade and produces dramatic improvement Dr Turner recommends treatment with antituberculous drugs, prednisone, and intrapericardial hydrocortisone

Ménière's Disease

Mr J F **JARVIS** described recent work on the microchemistry of the labyrinthine fluids and the finding of a high potassium content in the endolymph The electronystagmograph promises to widen understanding of nystagmus as a sign of labyrinthine disease

Treatment is still largely empirical and aims at removal of the cause, palliation of symptoms, and destruction of a useless and disturbing labyrinth

Allergic Dermatosis

Colonel H **WILLIAMSON** said that in treatment of allergic dermatosis the cortisone group of drugs is outstanding, these are harmless if given judiciously Possibly, disturbed cortisone secretion may explain the well-known association between emotional stress and allergic dermatosis

Histoplasmosis in East Africa

Dr P E C **MANSON-BAHR** said that *histoplasmosis* has been shown to occur in East Africa in the localised, disseminated, and benign pulmonary forms *Histoplasma capsulatum* lives in the soil in its mould phase and invades the body from dust. In Africa a large form—*H duboisii*—has been described. In the U S.A histoplasmosis is not uncommon, as is evident from small epidemics of the benign pulmonary form, a high prevalence of skin sensitivity, and a high prevalence of pulmonary calcification with positive skin histoplasmin tests *In* Africa all forms of the disease have been described, in East Africa Dockeray (1957) has described a localised granuloma of the pharynx, while Davies (1957) has described a fatal case of disseminated disease in a 2½-year-old European child

Dr Manson-Bahr described a case of benign pulmonary histoplasmosis or "cave disease" in a European male who had visited the Amboni caves near Tanga in Tanganyika, where the floor was covered in bat guano Fourteen days after exposure he became febrile with rigors and sweating There were no physical signs, but he had a persistent brassy non-productive cough *Radiographs* showed numerous coarse miliary granulomas throughout the lungs, which persisted for six months A histoplasmin skin test was positive No treatment was of any avail, but the patient gradually recovered

Stott (1954) found that of African adults in Kenya 8 5% reacted to histoplasmin, and of a group of miners from the Nyanza province 14 6% reacted Histoplasmin surveys can be expected to reveal further evidence of this disease in East Africa

Typhoid Fever at Mulago

Dr J M **VAIZEY** compared the cases of typhoid fever in Mulago Hospital in 1957, when chloramphenicol was available, with the cases in 1949, reported by Musoke[1], when chloramother more effective and less toxic agents are available Its major toxic effects on the kidney and eighth cranial nerve can probably be minimised to a certain extent by some caution in its use

---

[1] Musoke, L. K. *E. Afr Med J* 1952, 29, 209

The similarities and differences in the known chemical structure of kanamycin, neomycin, and the streptomycins and in the renal and eighth-nerve toxicity which they produce offer an opportunity to explore the specific relationships between the structure of these antibiotics and the toxic effects they produce This may lead to a better understanding of the basis of their production and possibly to means of preventing or alleviating them

Medicine and the Law

"False" Certificates

A DOCTOR was charged at Glasgow Sheriff Court under the National Insurance Act 1946 with making false statements on medical certificates [1]

The patient had had an operation on his right foot in June, 1957 While being treated as an outpatient he regularly called on his doctor for medical certificates, but on Dec. 7 he was sent to prison for 30 days for housebreaking

The patient's wife then twice called on the doctor and asked for her husband's certificates, explaining that he was in bed because his foot was swollen On the second occasion the doctor told her that he ought to see the patient before issuing the certificate. She confessed in court that she had lied because she was ashamed to admit that her husband was in prison.

It was submitted in defence that it would be outrageous to convict the doctor, who had done nothing wrong as the certificate was substantially accurate He was acquitted

Prison Sentence for Attempted Suicide

AT Cheltenham magistrates' court on July 17, an unemployed man of 59 was sentenced to six months' imprisonment for attempted suicide [2]

On June 8 the police had visited the man's house and found his wife dead in bed and the man sitting in a chair with a bullet embedded in his head He first appeared before the magistrates on June 26 when he pleaded guilty to attempted suicide and the possession of a revolver without a firearms certificate He was remanded for three weeks to Gloucester prison for a medical report

When he appeared before the magistrates again last week a police chief inspector said that the man had previous convictions for fraudulently drawing unemployment benefit, using threats, running away and leaving his children, assaulting the police, and committing an act of indecency The man admitted the convictions, but said that they were due to domestic trouble

The clerk to the magistrates said that the prison doctor's report recommended that the man should receive medical treatment, which could only be given at Coney Hill Mental Hospital, and that he should be put on probation for three years subject to his becoming a compulsory inpatient at that hospital The man was willing to comply with this condition

In sentencing him, the presiding magistrate said

"We think you could have done a lot better for yourself, you know You have not made all that effort to go straight or live honourably We have taken into account what has happened to you domestically and also we have considered your character We think the proper thing to do in your case is to send you to prison where you will receive the medical treatment you need"

---

In England Now

A Running Commentary by Peripatetic Correspondents

SEEN at 7 A M, the Wooloomooloo Private Hotel seemed to need a fire-brigade rather than a doctor The front hall was solid with blue smoke, through which Mr Robinson's Australian accent informed me that it was a fair cow as the kippers had exploded and set the curtains on fire while he and his wife were giving first-aid to the new lodger

"Cut her head on the wash-basin, doin' her early-morning reducing exercises I only wish I had some of her weight," said Mrs Robinson, whose two most prominent anatomical features were ears "Blood all over the new wallpaper, too—I told Fred we should have chosen the red geranium pattern Now we shall have to move the wardrobe in front" I interrupted Mr Robinson's disapproval of this idea by suggesting we went above cloud and saw the patient, but was told that there was no hurry as she was drinking tea and asking what there was for breakfast. I wondered whether the blow had damaged her olfactory nerves

Led by Mr Robinson, who resembled the Spectre of the Brocken, we stumbled upstairs in a hot vertical draught of kipper-smoke, to which each landing added contributions of onions, toast, coal-gas, and cabbage Permeating the whole, like harp music through a full orchestra, came suggestions of cat Charred fabrics, soot, and carbon copies of kippers fluttered about us, and shadows of inquisitive lodgers fled fearfully back into the reek at Mr Robinson's roars of reassurance These disembodied bellowings from the clouds produced a curiously Old Testament effect, heightened by a sudden thunderous hammering Mrs Robinson halted and clutched the bannister

"Nay dammit! That's Grandad stuck in't W again Ah told 'im not to go without 'is teeth in" I tried hopelessly to see the connection

"T'lock sticks if you lock it, so you've to whistle to keep folks out and Grandad can't whistle without 'is teeth so now t'lock's stuck"

"Just wouldn't it!" snorted Mr Robinson reappearing in red-eyed fury "An' all because that girl has to do slimming exercises to an (Australian) gramophone From the noise she makes every morning I reckon she puts the record on the floor, holds the needle on it with one hand, an' gallops round and round it"

"Nay, I blame her young man," said his wife, loyal to her sex. "I've asked her, but she just gives me a right sad, enemetic smile like that there portrait of who-is-it "

"The Mona Lisa?" I suggested

"Too —— right, Doc!" said Mr Robinson enthusiastically "She's the biggest moaner in the house"

"Listen who's talking!" retorted Mrs Robinson, adding accusingly "Ah'll bet that tea you gave 'er 'ad sugar in it"

"O' course it —— well did I was treating her for shock"

"She's reducing Sugar's bad for it."

"Well aren't you a silly woman, you silly woman," shouted Mr Robinson, shaking the bannisters "First things come first!"

"Like I say—she was fat before she was shocked "

I left them to it and entered the patient's room, where I put a dressing on a fat and dishevelled girl's scalp After thanking me, she said, "I don't know why I get so dizzy doing these exercises"

"I do," I said, looking at the gramophone "You're playing a 45 r p m record at 78"

* * *

We medicals sometimes cock a snook at our legal colleagues steeped in precedent and advancing, as we think, from before backwards But in the matter of space travel and moon habitation they are ahead of us As one of my peripatetic colleagues pointed out last week the psychiatric implications of the subject are still largely unexplored, yet the American Bar already has a committee on the law of outer space They cannot, however, shake off the earthy past altogether and quote the longer periods of administration than with streptomycin and dihydrostreptomycin, respectively, and the renal toxicity of kanamycin is much less marked than that of neomycin and requires much larger doses given over longer periods

Absorption and excretion from subcutaneous and intramuscular doses in animals and from intramuscular doses in human beings is rapid Peak concentrations from intramuscular doses are usually achieved in the serum in about 1 hour and these vary with, but do not exactly parallel, the size of the dose Exact dosage regimens cannot yet be established, but the rapid fall in blood levels indicates that intramuscular doses must be given at 6-hourly intervals in order to maintain adequate therapeutic levels, except for doses of 1 0 g which may be given at 8-hour or even 12-hour intervals Excretion of kanamycin is primarily into the urine and it is cleared by glomerular filtration only About one-half to as much as four-fifths or more of the intramuscularly administered dose is accounted for in the urine within 24 hours Oral doses are very poorly absorbed, and doses of 3–6 g daily appear to be effective in altering the bowel flora There appears to be no excessive binding of kanamycin to serum-protein and no evidence of cumulation Average peak concentrations in serum from doses of 0 5–1 0 g in adults are such as to permit inhibition of the more sensitive organisms, including staphylococci and mycobacteria, and of many susceptible but less sensitive ones (salmonella, shigella, and many strains of proteus), particularly with large doses

CLINICAL APPLICATION

Clinical results reported here from the intramuscular use of kanamycin were highly satisfactory in a large proportion of cases of staphylococcal infections, including many severe cases in which the organisms were resistant to other antibiotics, particularly penicillin, streptomycin, and the tetracyclines It appears to be highly effective in acute gonorrhœa in males and it was effective in most cases of severe anthrax infections The antibiotic has also proved effective in many acute and chronic infections of the urinary tract that resisted treatment with other antibiotics, but chronic infections with pseudomonas, enterococci, and some proteus strains appear to be resistant, and failures were reported in infections with such strains and in pneumococcal and streptococcal infections

Kanamycin given orally in doses of 4–8 g daily was found to be an effective inhibitor of aerobic intestinal bacteria comparable to neomycin and useful in the preoperative preparation for surgery of the large bowel It has been effective in the prevention and treatment of hepatic coma in a few patients with advanced cirrhosis of the liver in whom it has been tried and in reducing the level of ammonia in the blood of such patients, it apparently can be used together with chlorothiazide in such cases Favourable results were also reported from intramuscular or oral therapy in some salmonella and shigella infections, but not uniformly so in severe salmonella infections or typhoid Intraperitoneal instillation has been used successfully in established peritonitis and for peritoneal contaminations, but the possibility was raised that in some cases it may be followed by adverse respiratory effects when used in conjunction with ether or curare, although such a synergistic effect was not evidenced in dogs even with large doses of kanamycin

In the treatment of tuberculosis, the limited experience of American clinicians employing kanamycin alone in severe chronic and resistant cases suggests only that it exerts some favourable effects on the disease, but this was not very striking and resistance to kanamycin was rapidly acquired by the organisms Japanese experience with kanamycin given together with adequate daily doses of *p*-aminosalicylic acid (P A S) in more favourable cases, and as initial treatment, indicates that the two agents together exert clinical and bacteriological effects that are approximately comparable with streptomycin and P.A.S. used in the same manner It appears to be effective against infections with organisms that are resistant to streptomycin, isoniazid, or P A S' Kanamycin-resistant organisms that emerge during treatment are also resistant to neomycin, but streptomycin-resistance is not acquired in the process

TOXIC EFFECTS

Toxic effects observed thus far have generally been mild or moderate, serious toxicity has been encountered only rarely Local irritation from intramuscular injections has been slight and has rarely interfered with continued therapy Sensitisation, drug fever, and drug rashes appear to be infrequent, but eosinophilia appears to be frequent in patients treated for a week or longer

The major toxic effects are on the kidney and eighth cranial nerve Hyaline and granular casts are seen commonly in the urine, they may appear early, usually persist throughout treatment, and generally clear soon time after the treatment is stopped This is sometimes accompanied by the appearance or increase in leucocytes and occasionally by small amounts of albumin in the urine, but only rarely by elevation of blood-non-protein-nitrogen or by oliguria The evidence indicates that renal functional impairment, usually mild, occurs in more than a quarter of the patients, involves both glomerular and tubular function, and probably is wholly or largely reversible Reports on kanamycin treatment of patients with initially impaired renal function are too few to judge the effects in such cases, but such treatment should be undertaken with caution, where the underlying renal impairment is related to pyelonephritis, it may actually improve if the treatment favourably influences the infection

Vestibular damage appears to be infrequent, but loss of hearing, beginning in the high-frequency range, appears to be quite frequent on subacute or chronic administration of effective doses, especially with large doses and prolonged treatment Tinnitus is an early and important warning sign of eighth-nerve damage Audiometric tests should be done frequently during continuous administration, especially in patients with impaired renal function, or during prolonged treatment, or when large doses are used There is some evidence that the deafness may not always be bilateral, symmetrical, or permanent, it always appears and reaches its height during treatment Delayed appearance of deafness after stopping treatment was not noted, but the possibility of cumulative toxicity on retreatment must be considered

Unlike parenteral therapy, oral administration of kanamycin is usually well tolerated even in large doses and produces no toxicity except for occasional diarrhœa

CONCLUSION

Kanamycin thus appears to be a useful antibiotic for the treatment of certain troublesome bacterial infections It should not be used in the treatment of pneumococcal, streptococcal, brucella, or other infections in which the results have not been altogether favourable and for which

HAZARDS OF CHLOROTHIAZIDE THERAPY

SIR,—Chlorothiazide (' Saluric ') is now being extensively prescribed in general practice, for there can be little doubt as to its efficacy as a diuretic Certain precautions are, however, required in its use and our experience in a large hypertensive clinic suggests that prescribers are not always aware of the potential dangers of the new drug

Chlorothiazide under some circumstances causes a considerable diuresis of potassium in addition to that of sodium If the potassium is not replaced this can rapidly lead to hypokalæmia and symptoms of muscular weakness Hypokalæmia also potentiates the effect of digitalis derivatives and signs of digitalis overdosage may occur in digitalised patients given chlorothiazide Ideally, the plasma-potassium concentration should be followed serially during treatment, but in practice the administration of 3 g of potassium chloride on the days when chlorothiazide is given would appear to obviate the risk of the development of hypokalæmia If, however, renal failure is present potassium chloride should not be given unless the plasma-potassium concentration can be followed at short intervals

Chlorothiazide also potentiates the action of the hypotensive drugs mecamylamine and hexamethonium, and an excessive fall of blood-pressure may occur if chlorothiazide is given to a patient whose blood-pressure is already adequately controlled by ganglion-blocking drugs

We feel that these hazards of chlorothiazide therapy are not sufficiently widely appreciated

N.H.S. STAFF COLLEGE

SIR,—As Dr Fielding (July 12) referred to the Administrative Staff College of King Edward's Hospital Fund for London, a reply from me may not be out of place This staff college, of which I am chairman and which opened in 1951, has been endeavouring to do just what Dr Fielding advocates—to create " a working partnership between medical, nursing, and lay personnel to define each partner's proper sphere of activity, and to infuse that sense of common purpose which the service so badly needs "

The college has never aimed at providing refreshment solely for " lay " administrators Doctors have attended many of the courses planned for senior administrative officers, and courses have been held for physician-superintendents of mental hospitals, for finance officers, and even for hospital chaplains Meetings are arranged with the nurses attending the Fund's colleges for ward sisters and for matrons The possibility of offering a " mixed " course—doctors (and not just hospital doctors), nurses, and " lay " administrators—has been discussed, and even a short conference of chairmen of hospital management committees is in contemplation

The courses are all residential and discussion is the rule rather than formal lectures Many hundreds of administrative officers have passed through these staff colleges, and there is reason to believe that most, if not all, have benefited from the experience The colleges are not large—a discussion group of about a dozen seems best—so the numbers dealt with at any one time have to be restricted, nor can the Fund cater for the whole of the country Our ideas as to the future of the staff college are by no means fixed, so the Principal will welcome inquiries from interested doctors His address is Hospital Administrative Staff College, 2, Palace Court, London, W 2

King Edward's Hospital Fund for London,
34, King Street, E.C.2

WILSON JAMESON

RADIATION HAZARD IN ANTENATAL RADIOGRAPHY

SIR,—Dr Dempster (July 19) is to be congratulated on undertaking a prospective study of radiation hazards in antenatal radiography it is to be hoped that others will follow his example, thus accumulating the really large body of data which is necessary for study by this method In the meantime we would like to point out that a negative result obtained from a ten-year follow-up of 116 live-born infants in no way conflicts with the findings of our own survey, recently published in full[1]

The proportion of infants born in 1948 who died of malignant disease before reaching their tenth birthday is probably below 0 8 per 1000 If a typical pelvimetry examination doubles this risk, the odds against finding even 1 case in a sample of 116 would be nearly 5 to 1

BONE-MARROW TRANSPLANTATION IN BLOOD DISEASES

SIR,—Your leading article last week refers to the immunological obstacles encountered in this form of treatment To a certain extent the position has been clarified since the Boston conference and there now appear to be two separate problems

Rejection of the graft by the host occurs when enough immunologically competent cells remain after the onslaught of both disease and treatment The problem here is to discover an agent capable of destroying all the neoplastic cells as well as the native immune-reactive cells, and although this may seem a distant prospect there is, perhaps, one source of hope Hitherto, the effect of any form of therapy has depended on exploiting a difference between neoplastic and normal tissues of the same sort—i e , leukæmic cells versus normal marrow or lymphoid cells—whereas now the difference is widened and lies between neoplastic cells and susceptible normal cells of other organs (e g , intestinal mucosa), since one can afford to destroy all normal hæmopoietic cells This is a biochemical challenge

In the long run, however, the graft-versus-host reaction may be of greater importance A rejected graft can, perhaps, be replaced, but a rejected host will die of secondary disease The solution here, as indicated by the work of Medawar and his colleagues, lies in the use of fœtal material which may by virtue of " adoptive tolerance " accept an antigenically different host Both Barnes et al[2] and Uphoff[3] have published experiments demonstrating survival with fœtal tissue in strain combinations where adult tissue regularly causes fatal secondary disease

That fœtal cells can be safely used in man was demonstrated in one case by Thomas et al ,[4] and we have similarly treated seven cases without fatality In one case at least there appears to be evidence of a " take " as judged clinically, by serial marrow biopsies, and by the presence of circulating foreign erythrocytes Details will be reported in due course.

Meanwhile two further points deserve attention Not all histocompatibility barriers in mice can be overcome

Roman law of "ownership *ad coelum*" to mean extend upwards only to that point "where there is sufficient gaseous atmosphere to provide a measure of aerodynamic lift" beyond which is "*res extra commercium*" The moon, at present "*res Nullius*", is thus, we are told, capable of appropriation by effective occupation

Obviously, we should give more attention to health conditions in space and less to N H S conditions in this planet Couldn't the Royal Colleges, in the intervals between examinations, set up a committee on lunar nosology? Once we colonise the moon there are certain to be public-health problems—water-supply, sewage disposal, clean air, and so on—about which we could anticipate intelligently The first settlers, of course, should be our deaf mutes For them the soundless satellite will have no communication difficulties The second batch should be our bacteriologists to tend their cultures of cocci and viruses in an unfriendly land

I have always been a bit confused about the vagaries of lunar time and temperature, particularly on the blind side But they will provide interesting thesis pabulum for the next generation—the children who today smile at us Newtonians and are at home in this new cosmos of interchangeable matter and energy, elastic time, and curved space

* * *

The girl had wanted a certificate to be "off work" because of the "pressures in her head" She was the last patient and as I left the surgery feeling vaguely guilty, I wondered how I could justify that certificate

Curiously enough I found that same evening that the answer had been provided in 1560 by St Theresa To Nuns who "*have only a headache, but leave off going to the choir as* though that would kill them", she wrote

> "You may ask, why does the prioress give the dispensation? Perhaps if she knew your interior she would refuse, but as you inform her of your need and a doctor to whom you have said the same is not wanting to support you, and a friend or relative is weeping near, what can she do? She has a scruple lest she fail in charity, and she would rather you should be at fault than she"

How opposite to medicine But isn't there a sting in the tail of that quotation?

* * *

For most of us botany is a dim forgotten far-off thing of 1st M B long ago, and when our local medical society took an afternoon off from the discussion of typhoid and hookworm to visit the East African Forestry Research Organisation most of us learned for the first time of the ruthless racialism of the agricultural scientist In demonstration of plant diseases, a detailed clinical history with attention to sources of stress was perhaps hardly to be expected, but it was strange to find neither the patient nor the disease attracting much attention Instead the limelight was focused on the hero of the day—the resistant race Some judicious matchmaking followed, and by the third or fourth generation a paragon appeared—resistant yet fruitful to live happily ever after

Pondering on the possible application of such methods in human disease, I could picture the totalitarian countries forging ahead while the democracies rely on such half measures as a subsidised bride-price in cases approved by the Minister

* * *

Looking round at my colleagues the other day, all of them M—B, D, CH, S, R C S, or R C P, it struck me that there was room for yet another qualification There is one which I could, in all modesty and with a clear conscience, bestow on myself—M N (Nullorum Magister, or Master of None) Surely that would be an appropriate recognition for the hours of house-painting, plastering, wallpapering, gardening, cooking, baby-minding, washing up, carpet-laying, and car-tinkering which we all add to our more academic activities in these days of widening horizons and shrinking specialties

I hear that surgical caffeine-addicts are now trying to get their elevenses past the auditors by describing them as "opaque media" or "nutrient broth"

Letters to the Editor

THE PLACE OF THE RESEARCH INSTITUTE AND THE ADVANCE OF MEDICINE

SIR,—Although Sir Charles Harington's Linacre lecture[1] is most impressive in its range and understanding, I think there is one point of criticism of research institutes which he mentions briefly but does not answer—that research units withdraw the younger workers from university teaching

It is common ground that the research institutes require well-trained workers If the interests of university and research institutes conflict, Sir Charles suggests that those of the university should come first I do not think this is achieved by present policy

The most important part of the training of medical research-workers in this country is the course for an honours degree—for the Natural Science Tripos, Part II, at Cambridge, the Final Honours School at Oxford, the B Sc Special at London, and similar courses in the English provincial and some of the Scottish universities. For such a course it is essential to have at least half a dozen first-class university teachers to teach a variety of aspects of the subject These teachers must have sufficient research experience to have the respect of their pupils, some personal acquaintance with the borderland of knowledge, and the mental agility to meet a student in tutorial work on his own ground This last, alas, tends to disappear with increasing eminence and advancing years

It is extremely difficult to get such teachers and to keep them The attractions of research institutes include better laboratory equipment and facilities, more time for research, more technical assistance, freedom from correcting examination papers, and, in practice, better pay In addition, there is the prospect of becoming a head of a department by returning to the university in due course It is not surprising that an appreciable number of these men leave universities for research institutes

In return, the universities are offered men from research institutes whose sources of inspiration for research have dried up, and professors of eminence who have had no teaching experience at all, or none for the last ten to fifteen years While Oxford and Cambridge will no doubt continue to retain the tutors and supervisors they need, it is difficult for other universities to provide counter-attractions It seems that the supply of scientific man-power is limited, and that the share likely to reach the basic medical sciences is not likely to increase

I would therefore suggest to those responsible for long-term planning that research institutes should cease to recruit staff at or before PH D level, and that it should be exceptional to appoint anyone to established staff unless he had at least five years' teaching experience This would make the re-exportation to universities of both unsuccessful and the most successful research-workers rather easier As a longer-term measure, I suggest that, instead of building further isolated research institutes, every effort should be made to site research units within universities and that their staff should take part in the teaching of undergraduates at honours level There are difficulties in this proposal, but in some universities they have been successfully overcome

Wroblewski et al deal with alanine-ketoglutaric transaminase as a more sensitive index of hepatic damage We feel therefore that it is unjust to attribute to Wroblewski and his colleagues the discovery of the diagnostic value of the serum-transaminase activities in virus hepatitis

We should like to draw the attention of Dr O'Brien and his colleagues (June 14, p 1245) to a report[12] on both the transaminase activities and their ratio, on phosphoglucomutase activity, and on fumarase activity as indices of the effectiveness of prednisone therapy in virus hepatitis

NO MORE NEOLOGISMS?

SIR,—We must all sympathise with Mr Norman Lake's dilemma Nevertheless his conclusion, at least as reported in your columns (July 5, p 40), that the addition of the new word "hæmorheology" to medical jargon is justified must not go unchallenged. The term seems to have been invented by Dr A L. Copley, and again to quote your report of the meeting at Charing Cross Hospital, covers "the deformation and flow—i e, rheological—properties of cellular and plasmatic components of blood in macroscopic, microscopic and sub-microscopic dimensions and the rheological properties of vessel structure with which blood comes in direct contact"

The subject as defined by Dr Copley has been studied before, not entirely without success, by such men as Harvey, Malpighi, Lister, Krogh, and Florey, to name only a few As far as I can recall they did not find that in order to study what was happening to the blood-flow in relation to the vessel wall a new term was necessary Why then should it be needed now? Is it to clarify or to obscure? Unfortunately the latter is the only tenable conclusion

This issue is so trifling in itself that I would not have bothered to raise it were it not that this is no isolated instance It is merely a rather striking example of a growing tendency among medical and other scientific writers to obscure their own thoughts and to hide them from other people by clothing them in unnecessary jargon Thus, a paper by a very talented scientist and writer who is a personal friend of mine contains the following sentence "A rate of infusion of 15 mg per kg per hour (of chlorothiazide) *induced natriuresis, kaluresis, chloruresis and bicarbonate excretion*" Now the unfortunate scientist who is not a renal physiologist cannot find these words in a dictionary, unless he knows Greek he cannot be sure of their meaning, and even then it can only be a guess Why did not he write "increased the excretion of sodium, potassium, chloride, and bicarbonate" It would have been no less accurate, rather shorter, and easily understood by all The reason was clearly that he fell unthinkingly into one of the bad habits of the time As to why this bad habit has arisen at all is a question which perhaps you may allow me to discuss in your columns on another occasion

Now this is a very serious problem, the more serious perhaps because it is so little ventilated It is the ancient and honourable objective of men of science to discover scientific truth by observation and experiment and to make it known The introduction and use of unnecessary scientific jargon seems to me to be flatly opposed to this objective Is it too much to hope, Sir, that your journal, which has so often given a courageous lead in the past, should declare that in the future it intends to uphold the dignity and purity of the English language and not to allow the use of technical neologisms unless they are clearly defined and an unanswerable case made out for their use

Oxford GEORGE PICKERING

SIR,—Reading in *The Lancet* during 1957 only those articles likely to interest a general physician, I came across the following words, which appear neither in the *Concise Oxford Dictionary* nor in the latest (1957) edition *Stedman's Medical Dictionary*

Allergology
centrencephalic
oxalosis
chylomicra
ephebiatrics
ataractics
algometer
hypohyperparathyroidism
polypectomy
pathophysiology
cholangiolitis
neurosophical
dysraphicus
undervascularised
cardiomyopathy
rhabdomyolysis
transfusionists
centrizonal
thoracologist
histogram
ataralgesia
pulhestibs

In addition, the following words, though listed in Stedman, would be difficult to justify

Cholestasis
antigenicity
hyposthenuria
angiolymphitis
defibrillation
anæsthetologist
uricosuric
normovolæmic
phlebarteriectasis
angiology

Stedman's Dictionary now contains 1656 large pages Since the 1953 edition, over 4000 new words have been added—nearly 3 new words a day When is this verbal flood going to abate? You, Sir, have added to the deluge, but I plead with you not to allow any further new words to appear in *The Lancet* unless a very good case can be made out for them

Some new words are merely ugly cacophonous polysyllabic accretions, more appropriate to German than to English Many other new words have been perpetrated because the writer has been leaning over backwards to avoid the suffix "itis" It is true that "itis" in Greek signifies inflammation, but by "inflammation" the Greeks referred to any lesion which produced either swelling or redness or heat—any one and not necessarily all three Examiners, it seems to me, are especially prone to ill-justified quibbling over the suffix "itis", and a well-known textbook, after insisting that the term "retrobulbar neuritis" be reserved for inflammatory lesions, mentions that "an optic neuritis is secondary to a retinopathy" The time is ripe for an agreement that "itis" implies "a lesion of", not necessarily an inflammation Otherwise future journals will add still more needless new words to spondylosis, neuropathy, retinopathy, cheilosis, myelopathy, &c

Some writers have replaced the prefix "a" (or "an") meaning "without" by "hypo", which implies a diminution rather than a complete absence, thus hypoxia, hypalgesia, &c But we all realise that complete absence of anything is rare in clinical medicine

Surely language is determined largely by common usage, and new words should not be invented purely on etymological grounds—which are often inaccurate

London, W 1 M H PAPPWORTH

*** Were we to insist, as Sir George Pickering suggests, on an "unanswerable" case before admitting a technical neologism to our columns, we should be putting what seems to us an unreasonable constraint on contributors, and if we adopted Dr Pappworth's relentless standards, we had better put on our contents page "no neologisms allowed" Rightly or wrongly, we judge the ones that come before us less strictly than either of our correspondents, in the belief that the construction of a new word is sometimes a praiseworthy, though not always successful, attempt to improve communication Some of the words by using fœtal tissue (Uphoff, personal communication) What then are the equivalent distinctions in man? Are they perhaps identical to the major blood-group antigens? Secondly, is it desirable to include with the marrow transplant as much lymphoid tissue as possible, in particular splenic cells, with a view to providing the means of resistance to the infections which inevitably occur in these patients? If secondary disease can with certainty be avoided the answer is yes, but it yet remains to be seen how soon fœtal cells transferred to an adult environment become capable of immune reactivity

WORLD HEALTH ORGANISATION

SIR,—In his review (July 12) of the first decade of the World Health Organisation, Dr H S Gear restates the principles on which the Organisation was conceived, and examines how far they have been applied One of these principles is that membership should be universal, and Dr Gear refers to 88 States which belong Undoubtedly the most serious defect is that China is "represented" by the Government in Formosa The loss is not only China's, since it is clearly undesirable epidemiologically that a vast land mass and 650 million people should not contribute to, as well as share in, international health coverage At Geneva recently a senior W H O official gave me an example from the recent influenza pandemic The virus was first isolated in China, and had that country been a member of W H O the strain, as well as early epidemiological information on the epidemic, would have been automatically made available to the Organisation As it was, it appears that three valuable months were lost before the virus was isolated elsewhere

London, N W 3

P D'ARCY HART

WORKING PARTY ON HOSPITAL MEDICAL STAFFING

SIR,—The consultants and specialists of the regional-board hospitals note with concern that the working party to inquire into the staffing of hospitals does not contain a direct representative of the provincial non-undergraduate-teaching-hospital staffs Most of the hospital work in the country is done in regional hospitals, whose staff comprise the greater proportion of the nation's specialists Most of the problems involved in staffing at consultant and registrar level concern these hospitals It is our earnest hope that every endeavour will be made to take evidence from the staffs of such hospitals in order that the problems involved may be effectively solved

It is possible that the extent of staffing difficulties and the pressing conditions which have led to the present situation have never been fully realised, because those at the helm on various consultant committees have been trained and work mainly in teaching hospitals where the conditions of service are different and more leisurely The turnover of patients, both emergency and routine, is higher in the regional-board hospitals Members of non-teaching hospitals have contributed generously to the success of the regional hospital service, but the "slack" in their establishments was taken up years ago and new consultant and registrar establishments are overdue

London, W 1

HAROLD DODD
President Regional Hospitals Consultant and Specialist Association

CRASH-HELMETS

SIR,—During the past weeks there has been a good deal of correspondence in your columns about the relatively small number of people killed and injured while boxing, yet all the time far more people are involved in motor cycle accidents Time and again the story is the same boys and young men brought into hospital with head injuries so severe that it seems impossible that they will ever recover (in fact many do not)—and all this very largely because they were not wearing crash-helmets Surely, Sir, to make a motor-cyclist wear a crash-helmet is no more an infringement of his personal liberty than it is to make an industrial worker wear protective clothing or to make a ship's passengers do boat-drill If these young men will not take reasonable precaution to protect themselves of their own accord they must be made to do so by the community The law would be easy to enforce—one warning and then a summons

Worthing Hospital,
Sussex

P J G SIMONS

TRANSAMINASE ACTIVITY IN LIVER DISEASE

SIR,—We have read the two papers on this subject in your issue of June 14, and as neither of them refers to the work published by us since April, 1955, on the diagnostic value of serum-transaminase activity in virus hepatitis, may we briefly summarise our contribution to the argument?

Since our first papers[1 2] appeared we have been able to demonstrate that in virus hepatitis (1) both the aspartic- and alanine-ketoglutaric transaminase (that is to say, glutamic oxaloacetic and glutamic-pyruvic) activities of the serum show a remarkable increase (twenty to forty times), (2) the ratio (aspartic-ketoglutaric/alanine-ketoglutaric) becomes strongly inverted, falling from the normal mean value, in healthy subjects, of 1 24 to a mean value of 0 64, (3) this pattern is typical of virus hepatitis and is not generally found in any other of the hepatic, icteric, and anicteric diseases investigated (bacterial hepatocholangitis, hepatic cirrhosis, the liver of congestive heart-failure, occlusive jaundice, &c), (4) the aspartic-ketoglutaric/alanine-ketoglutaric ratio remains persistently inverted during recovery, when the absolute values of the serum-transaminase activities again reach almost normal levels, so that a retrospective diagnosis of virus hepatitis is often possible

All our subsequent findings,[3–6] as well as those of other workers, have confirmed our original statements

The inverted ratio can also be found in rare cases of occlusive icterus, hepatic neoplasm, and hepatic amœbiasis, but without the high enzyme activities of virus hepatitis, so that the enzyme pattern we described remains a valuable diagnostic test in this disease

The first data of Wróblewski and LaDue[7] on serum-transaminase activity in virus hepatitis were published in September, 1955—several months after our first papers—and dealt only with the aspartic-ketoglutaric transaminase Previously Wróblewski and LaDue[8] reported high aspartic-ketoglutaric-transaminase activity in clinical and experimental hepatic damage, but no numerical data were published, and no connection was mentioned with the diagnostic value of this determination in virus hepatitis Only in later papers[9–11] did

ANÆSTHESIA FOR THE EMPHYSEMATOUS

Sir,—I should like to endorse the plea by Dr Wynn and Dr Brooks (July 5) that anæsthetists should have facilities for obtaining not only the CO_2-combining-power but also the pH. A CO_2-combining-power of 65 vols % at a pH of 7.35 would be compatible with normality, but a CO_2-combining-power of 65 vols % at a pH of 7.25 would indicate uncompensated CO_2 retention. This acid-base balance of the venous plasma has been illustrated previously.[1]

Hull W. N. Rollason

LONDON MEDICAL ORCHESTRA

Sir,—I would crave the courtesy of your columns to bring to the notice of the musically minded the London Medical Orchestra, who are anxious to recruit players for the coming season starting in October.

There is something particularly enjoyable in the amateur orchestra and some great figures in our profession have found it a refreshing distraction, two who come readily to mind were His and Billroth (the friend of Brahms). Moreover, the present President of the Royal College of Physicians is at times observed performing valiantly in our ranks under the proficient conductorship of Doctor Ucko.

With the help of distinguished soloists this orchestra has raised over £400 this year for the Imperial Cancer Research Fund by public concerts, and will continue to help medical charities.

Dr E. V. Slaughter of 6, Oxford Court, London, W.3, would be glad to hear from any who are interested.

A. Dickson Wright
London, W.1 President, London Medical Orchestra

FLAMMABLE CLOTHING

Commenting on a discussion at the annual representative meeting of the British Medical Association in Birmingham this month, Mr S. G. Willby, press officer of the British Standards Institution (2, Park Street, London, W.1), writes:

It was disappointing to learn that the meeting saw fit to pass unanimously a Manchester motion expressing dissatisfaction with the report of a B.S.I. committee about flammable clothing.

It is indeed highly desirable, as Dr Marion Reekie, who sponsored the motion, said, that manufacturers should produce attractive flame-resistant clothing at prices only a little above those of normal garments. The report urges that this should be done. But it is a fact that at present all garments worn by children—apart from those made from certain of the synthetic fibres, from heavy woollen cloths, and from a few specially treated fabrics—are liable to catch fire. Our report sought to warn parents of this fact and of the contingent dangers.

It is a delusion to suppose that there exist two ranges of fabrics, one safe and the other dangerous. There are fabrics with flame-resistant finishes on the market, but research is still proceeding to devise finishes which will outlast the washing which every child's garment must undergo. And until shoppers demand and retailers stock these fabrics their prices are unlikely to fall appreciably.

What our report did bring out was that the design of garments may be fully as dangerous as their fabric. If a child wearing a nightdress stands close to an unguarded coal fire, up-draught may well suck the garment against the fire, and the child would be burnt even though the nightdress was made of flame-resistant fabric.

The campaign for guarding fires, which has now been vigorously taken up by the Government, is not in any way a substitute for the development of flame-resistant fabrics nor a concession to human frailty; it is a step towards preserving human life.

Parliament

Doctors in Parking Meter Areas

In the House of Lords on July 5 Earl Howe asked the Government whether, in the rules governing the operation of parking meters in areas where they were installed, it was intended to make any special regulations to meet the needs of professional men, their clients, or their patients.—Lord Mancroft replied: No special provision for professional men, their clients, or patients was proposed by the local authority or included in the only parking meter order so far made—which is operating in North West Mayfair. Any local authority proposing such an order may include in it such exemptions under section 21 (4) of the Road Traffic Act, 1956, as they may wish, but I cannot anticipate the decisions of the Minister on any such applications. Earl Howe: Does not the noble Lord think that in the case of people, perhaps suffering from grave injuries, who are going to see their medical advisers, some relaxation of the parking meter regulations as they stand should be incorporated in any further order made for the same purpose?—Lord Mancroft: My Lords, it does not actually matter what I think. What does matter is what representations are made by the local authorities to the Minister when he has heard all the interests concerned. In the case to which I have referred I understand that no representations were made, and on the only other Order (from Marylebone Borough Council) before the Minister representations were made. The matter is still under consideration.

QUESTION TIME

Security at Broadmoor

In answer to a question Mr Derek Walker-Smith, Minister of Health, said that though he had not yet received the full report of the Board of Control inquiry into the recent escape from the institution he had received a summary of their main findings. They found that the saw used by the patient had been introduced into the institution from outside. They recommended that:

(1) Search of patients after visiting days should be intensified.

(2) There should be no exception to the rule that the siren is to be sounded immediately the escape of a dangerous patient is known.

(3) The strength of the night staff on duty in the block from which Mitchell escaped should be increased at once.

(4) Alterations to the walls of the institution to increase their security at strategic points should be commenced immediately.

They have already given instructions for the implementation of these recommendations.

Expenditure on Social Services

In 1956 the Exchequer spent £1554 million on the social services, the National Insurance funds £641 million, and the local authorities £704 million. The total, £2899 million, is 17.6% of the national income. The specific grants from the central Government to the local authorities are included in the Exchequer's contribution.

Tuberculosis Beds

In the past five years the number of hospital beds in England and Wales allocated to tuberculosis has fallen by 8935.

Emergency Morphine Supplies at Docks

After consultation between the Home Office and other departments, the Home Secretary has decided, as a special case, to authorise the keeping of supplies of morphine for use by nurses in an emergency at port medical centres where suitable safeguards can be arranged.

Merit Awards

The number of merit awards in payment in England and Wales at the end of 1957 was: 276 at the rate of £2500, 690 at the rate of £1500, 1377 at the rate of £500. The total amount paid is estimated at £1,450,000 in 1949 (the first full year) and £1,960,000 in 1957.

mentioned in the preceding letters are clearly less acceptable than others, but some in Dr Pappworth's list (ephebiatrics and ataralgesia, for instance) were coined for a clear purpose and are, we think, justifiable, though tentative, creations In the centenary year of Darwin's *Origin of Species*, it seems only decent to allow a little scope to Natural Selection —Ed L

SMALLPOX VACCINATION

Sir,—I have used the antecubital site for vaccination for more than ten years, and to the advantages mentioned by Professor Saunders (June 28) I would like to add one which, next to the cosmetic effect, appeals perhaps most to patients—that they can lie down in a bath resting the elbow on the sponge tray Furthermore, it is possible to sleep on that side, and the site is more easily protected in crowds, and is out of the way of those hearty fellows who greet one with an affectionate squeeze of the upper arm The only disadvantage is that in the case of a severe reaction the sling must be adjusted so that the angle of the elbow-joint is obtuse—a right-angle or less impedes the flow both in the veins and in the lymphatics

London, W 1 E G Huxley Cowen

5-HYDROXYINDOLEACETIC ACID IN STEATORRHŒA

Sir,—In your report of the meeting of the American Gastroenterological Association (June 21, p 1313) you quote the statement that the urinary excretion of 5-hydroxyindoleacetic-acid (5-H I A A) is increased in the patient with idiopathic steatorrhœa in relapse, but not in other types of steatorrhœa If this is confirmed it will be most helpful in the diagnosis of this condition, but a sprue-like state has been described in the carcinoid syndrome,[1] and I have recorded a case of idiopathic steatorrhœa, in which the diagnosis was confirmed by jejunal and ileal biopsy, with a normal urinary excretion of 5-H I A A [2]

Groote Schuur Hospital,
Cape Town Dennis M Krikler

DIASTOLIC PRESSURE AND MALIGNANT HYPERTENSION

Sir,—We have studied a group of 284 unselected hospital inpatients with hypertension, according to two scales of pressure (1) a scale of diastolic blood-pressure (D B P) divided into 6 " levels " of 15 mm Hg each, ranging from 85 to 160 mm and over, and (2) a scale of diastolic age-sex-adjusted-score (D A A S),[3] divided into 6 " degrees " of 15 mm each, ranging from 0 to 75 mm and over These two scales were correlated with the degree of change in the optic fundus, according to Keith, Wagener, and Baker, and with the frequency of electrocardiographic left ventricular hypertrophy, congestive cardiac failure, electrocardiographic coronary damage, and cerebrovascular accidents The ætiology of hypertension was not considered in this study

In the D B P scale 22% of the cases were over 130 mm (4th level) 26 5% of those with the malignant type of fundus were under 130 mm 83 3% of patients over 160 mm (6th level) had the malignant type of fundus, and none of the patients over 160 mm had a normal fundus

These figures were different in the D A A S scale 34 5% of cases were over 45 mm (4th degree), and only 10% of th with malignant type of fundus were under 45 mm Only 46 of patients over 75 mm (6th degree) had the malignant type of fundus, and 16 6% of cases over 75 mm had a normal fundus

According to this study, a diastolic pressure expressed in D A A S of 45 mm Hg (4th degree) marks the start of th malignant phase This level is more accurate than the classic D B P level of 130 mm The following table gives this malignant incipient level in D B P by age and sex

Age Men	10–13	14–25	26–38	39–51	52–70	71–84	
Women		10–23	24–34	35–43	44–54	54–64	65–81
D B P (mm Hg)	110	115	120	125	130	135	140

The D A A S makes it possible to identify patients with malignant hypertension before changes are evident in the fundus and before left ventricular hypertrophy develops It also allows the significance of high blood-pressure to be assessed in old people

The frequency of congestive failure and of left ventricular hypertrophy is related directly to the increase in diastolic pressure The frequency of the electrocardiographic coronary changes and of cerebrovascular accidents is not related to that increase

Aguirre Hospital,
University of Chile Ricardo Cruz-Coke

INTESTINAL ANGINA

Sir,—It is surprising to me that Dr Whiteside's letter of June 21 has passed without comment I believe that upper abdominal pain or discomfort or feelings of distension are not uncommon symptoms of ischæmic cardiac disease

Recently, one of these patients described her symptoms rather aptly, saying " When I walk fast I feel that I have too much air in my stomach, and none at all in my chest " She located her " stomach " about the centre of the epigastrium

A few months ago I saw an intelligent 38-year-old man who complained of a transient oppressive pain following severe exertion Electrocardiography suggested a small anterior cardiac infarct He was quite adamant that the location of his pain was not alone below the xiphisternum but was actually subumbilical

Limerick R Holmes

DEATH OF A BOXER

Sir,—I do not recollect that any of your correspondents so far has drawn a distinction between amateur and professional boxing When I was a member of my university boxing club 28 years ago the duration of an amateur contest was limited to three 2-minute rounds There is a vast difference between this and the professional contest of ten to fifteen 3-minute rounds towards the end of which muscular fatigue of the neck and trunk muscles must reduce the defence to a blow on the head Amateur boxing was then, and I presume still is, carefully controlled by a referee and two judges In my experience where there was an obvious discrepancy in skill the contest was speedily stopped

The suggestion of Dr Pakenham-Walsh (June 21) that because boxing is taught in schools and boys' clubs therefore professional boxing will continue to thrive seems to me a non sequitur I have personally only once watched professional boxing, and left nauseated after half an hour No doubt your correspondent draws on personal experience when he writes that wrestling is safer and more efficient, although I read in a newspaper report the other day of a wrestling match in which the rival contestants were removed unconscious from the ring

tion that local authorities should be given more help from central funds for the development of their welfare services for the disabled, an allowance for this purpose will be included in the general grant which it is proposed to substitute in 1959–60 for the present specific grants The Minister also asks authorities who are not yet providing welfare services for the handicapped to reconsider the position He is aware that many of them are supporting the provision of these services by voluntary organisations, but he is satisfied that when the authorities themselves undertake this responsibility (in full cooperation with the voluntary organisations) more complete and uniform services can be given.

The Minister especially supports the Piercy Committee's recommendations for more hostels for the tuberculous and for convalescent mental patients and for short-stay accommodation for the elderly

DENTAL ANCILLARIES

The shortage of dentists is described as "universal", and in no country is the dental profession increasing as fast as the population. On the other hand, experience has shown that, by delegating part of their work to trained assistants, dental surgeons can look after many more people. For this reason the W.H.O Expert Committee on Auxiliary Dental Personnel, at their meeting held in Geneva at the beginning of this month, laid stress on the need for dental-health teams each supervised by a dentist using two or more assistants highly trained but in a limited field. Such teams (the committee think) could be introduced with advantage into the established dental programme of economically advanced countries as well as in building up services in areas which at present have little or no dental care.

Among the auxiliaries in the team, the committee include chairside assistants, dental technicians dental hygienists, and school dental nurses, but they recognise that the training and employment of such personnel will need to be graduated according to the particular requirements of the area. Since the auxiliaries—of whatever kind—must work under the direction of fully qualified dentists, who take responsibility for what they do, the committee recommend that attention should be given to the education of dentists in utilising the help of assistants

For areas where there is at present no professional dental service the committee propose the training of a special type of personnel At first, perhaps these could do no more than relieve pain and cope with emergencies, but they would also work in teams, and their training would be planned to allow for additional and continuing education as the service develops

The following are among the figures supplied to the committee by the International Dental Federation

Country	*Number of qualified dentists*	*Population*	*Ratio*
Australia	3900	2,125,000	1 2250
Canada	5564	16,589 000	1 2981
Germany	33,694	52,521,300	1 1559
Indonesia	300	80,000,000	1 270,000
Netherlands	2500	11,000 000	1 4400
South Africa	1250	13,500 000	1 10 800
United Kingdom	16,000	51,200,000	1 3792
United States of America	90,000	173 000,000	1 1900

Participating in the committee were Dr J Llewellyn Saunders (New Zealand), chairman, Dr James Deeny (Dublin), Dr A. I Domnikov (Moscow), Dr A. Maxwell Horsnell (London), Dr O K. Oswald (Gothenburg), Dr Shailer Peterson (Chicago), and Dr C. J Sundram (Penang)

LIGHT DIETS IN HOSPITAL

The Hospital Catering Advisory Service (King Edward's Hospital Fund for London) has issued a memorandum on "Light Diets". This term is vague and undesirable, but is still commonly used in hospitals to denote diets which are nutritious and easily digested but at the same time varied and tempting. Suitable recipes for soups, main dishes, puddings, and sauces are included.

Copies may be had from the Fund, 34, King Street, London, E C.2 (1s post free)

The Cameron prize was awarded to Prof Charles B Huggins, of the University of Chicago, in recognition of his researches on the hormonal treatment of cancer and particularly for his introduction of the treatment of prostatic carcinoma by oestrogens

Dr. K. W Donald reader in medicine in the University of Birmingham, has been appointed to the chair of medicine in succession to Sir Stanley Davidson, who retires at the end of March.

Dr Donald, who is 46 years of age, was educated at Emmanuel College, Cambridge, and St. Bartholomew's Hospital, qualifying in 1936 During the late war he served with the Royal Navy as senior medical officer with a destroyer flotilla and was awarded the D.S.O for his work in the Narvik action. In 1942 he created the Admiralty experimental diving unit and personally conducted investigations into survival in closed spaces, resuscitation, oxygen poisoning, and carbon-dioxide intoxication. Much of his published work has dealt with high-pressure physiology and cardio-respiratory function in health and disease. After the war he returned to Barts as chief assistant in the medical professorial unit. In 1948 he spent a year in the United States with a Rockefeller fellowship, and on his return he was appointed senior lecturer in medicine at the Institute of Diseases of the Chest, Brompton. In 1950 he became senior lecturer in medicine in the University of Birmingham and assistant physician to the Queen Elizabeth Hospital. Five years later he was appointed first assistant to the Birmingham chair of medicine. He is a consultant to the Royal Navy and chairman of the Under-Water Physiology Committee He is secretary of the Medical Research Council committee on breathing apparatus for protection against fumes and gases. He is also honorary consultant to the National Coal Board.

Dr J D Sleigh has been appointed lecturer in bacteriology

Obituary

EDWARD WALKER BAIN

M B *Lond*, F R C S

Mr Bain, honorary consulting surgeon to the ear, nose, and throat department of the Leeds General Infirmary, has died at his home in Arkendale at the age of 82

He qualified from the London Hospital in 1902, and after postgraduate study in Vienna took the F R C S in 1907 He held a senior clinical assistantship in the ear, nose, and throat department of the London Hospital and was for a time assistant surgeon at the Metroplitan Ear, Nose, and Throat Hospital before he was appointed to the staff of the Leeds General Infirmary in 1912 as the first surgeon of its new ear, nose, and throat department He was lecturer in E N T surgery at the University of Leeds and he also held appointments at St James's Hospital, Leeds, and at Castleford and Normanton During the first world war he served as captain in the R A M C, in the military hospital at Beckett Park, Leeds He retired from his hospital appointments in 1937, but during the late war he was recalled to his old department at the Leeds General Infirmary and he worked there until 1945

E S writes

As a surgeon, Mr Bain was careful, skilful, and deliberate A man of few words with a most equable temperament he was always courteous and dignified He had an extensive practice throughout the three ridings of Yorkshire, travelling far in the days of mastoid emergencies, and his advice was widely sought in consultations throughout the county

He had many interests outside his professional work, but gardening was his chief hobby During his later years he developed a great interest in fly fishing and he was a keen member of the Harrogate Fly Fishers Club He retired to the country, where he spent his last few years still much attached to his gardening Bill Bain will be mourned by all those who knew him, particularly residents and fellow consultants of the years after the first world war who will always remember his kindness and hospitality

Notes and News

MEDICAL SCHOOL FOR RHODESIA

ON Feb 1 we recorded some of the conclusions of the committee which is advising the University College of Rhodesia and Nyasaland on whether to set up a medical school The full report, now published as a supplement to the June issue of the *Central African Journal of Medicine*, points out that for the supply of doctors the Federation at present depends entirely on other countries

> "Apart from there being a limit to the extent to which a country can rely on borrowed talent, on the two counts of training and supply the situation is not becoming any easier while the demand is increasing In Great Britain there is one practising doctor to under 930 of the population, the corresponding figure in the Federation is one to approximately 13,000, but in ten years' time, if there is no considerable increase in the number of doctors, this already fantastic figure will have reached the level of one to 17,500 The number of doctors to the African population is very much less than the present over-all figure of one to 13,000—some put it at one to 37,000, and in one district at least (Mrewa) it is one to over 80,000 There is, moreover, a grave lack of full consultants to deal with the African population"
>
> "In two respects in which the medical services of the Federation are particularly at fault—maldistribution of medical personnel and lack of junior resident medical officers in hospitals—the advent of a medical school could bring about an immense improvement"

A new school should, it is suggested, be established within the next two or three years, with clinical teaching at the (suitably developed) African hospital at Harari, 7 miles from the University College at Salisbury It should at first have an intake of 25 students a year, and the course should lead to a qualification registrable by the General Medical Council

The members of the committee are Mr L Farrer-Brown (chairman), Prof W M Arnott, Prof T H Davey, Prof A D M Greenfield, Prof P B Medawar, Dr Honor Smith, and Prof R Milnes Walker

PIERCY'S RELIQUES

THE Minister of Health and the Secretary of State for Scotland have sent memoranda[1] [H M (58) 57 and S H M 58/54] to the hospital authorities drawing their attention to points in the report of the Interdepartmental Committee on the Rehabilitation, Training, and Resettlement of Disabled Persons[2]

The Minister asks the English boards to review their facilities and to consider what reorganisation may be desirable He suggests that they may find it convenient to begin by concentrating on two or three selected areas in their region. The matters which he would like to see included in the review are the general supervision and coordination of facilities, the assessment of disability, and the need for additional facilities, such as sufficient space for active physiotherapy, or, in the occupational-therapy department, for simple factory work or training for adjustment to home conditions In rural areas there may also be need for residential accommodation for selected patients who need a planned and fairly active convalescence

The Scottish report necessarily covers much of the same ground Also it suggests that each region should have at least one consultant who would give most, but not the whole, of his time to the rehabilitation service "He might advise the regional hospital board, be available to the specialists for consultation in difficult cases, and in his own unit undertake to pioneer the development of rehabilitation services" The Department of Health looks forward to the time when every major general hospital will have a rehabilitation department offering the full range of hospital facilities to outpatients A practical start, it thinks, might be made now with an experimental comprehensive rehabilitation and assessment centre

The Minister of Health in a memorandum to local authorities[3] says that, in view of the Piercy Committee's recommenda-

THE TREATMENT OF IDIOPATHIC THROMBOCYTOPENIC PURPURA

A REVIEW OF NINETY-THREE CASES

E J. WATSON-WILLIAMS
M B Camb , M R C P
LATE REGISTRAR, DEPARTMENT OF MEDICINE *

A I S MACPHERSON
Ch M Edin , F R C S E
SURGEON, EDINBURGH ROYAL INFIRMARY,
LECTURER, DEPARTMENT OF CLINICAL SURGERY

SIR STANLEY DAVIDSON
M D Edin , F R C P E , F R C P
REGIUS PROFESSOR OF MEDICINE

UNIVERSITY OF EDINBURGH

IN 1776 Werlhof described the purpuric condition now recognised to be associated with a deficiency in the number of circulating platelets Nothing that could influence the course of the disease was known until 1916, when Kaznelson reported a good result following splenectomy, and for the next thirty-five years this was accepted as the only effective treatment of idiopathic thrombocytopenic purpura After the introduction of corticotrophin and cortisone into clinical practice, it was observed that their use in high dosage was followed by improvement in some patients with this condition (Medical Research Council Hæmatology Panel reports 1952, 1953, 1955)

Material

93 patients (28 males, 65 females), in whom the diagnosis of idiopathic thrombocytopenic purpura was satisfactorily established, form the basis of this paper

Patients with thrombocytopenia associated with other hæmatological disorders or with portal hypertension, or following the use of drugs or other substances known to produce platelet deficiency, have been excluded All had hæmorrhagic manifestations and less than 100,000 platelets per c mm of blood on at least two occasions 85 patients had a prolonged bleeding-time, and of 70 in whom it was estimated, 58 had an increased capillary fragility Smears of bone-marrow were examined in 44 cases In all, the number of megakaryocytes was normal or increased, and no abnormality of the red cells or white cells was seen In no case was the spleen palpable, and the weight of spleens removed surgically ranged from 50 g to 230 g (average 120 g , which is within the limits of normal) (McNee 1931)

13 of the cases reviewed by Robson (1949) and 8 of those reviewed by Davidson et al (1952) have been followed up for a further period and are included in the present review 63 patients have been followed up for at least four years

Methods

Platelets were counted by the direct method in a counting-chamber, using capillary blood Since 1938, all examinations have been performed in the department of medicine of Edinburgh University, the great majority by one technician Normal values in this laboratory range from 200,000 to 500,000 per c mm of blood

The bleeding-time was measured either by Duke's method (Duke 1915) or by Ivy's method (Biggs and Macfarlane 1953) The normal range is from one to six minutes

Capillary fragility was estimated, in most instances, by the negative suction method (Scarborough 1941) Sometimes it was examined by the tourniquet method, the cuff being inflated to 100 mm Hg for five minutes The appearance at this time of six or more petechiæ within a circle 2 5 cm in diameter was considered abnormal

Throughout the series the method of *splenectomy* has been, with slight modifications, that practised by the late Sir David Wilkie

A few points deserve emphasis The stomach was emptied immediately before operation, and kept empty throughout by passing and retaining in position a stomach tube The incision usually made was left paramedian through or displacing the upper part of the left rectus muscle, but in a few patients with a wide costal angle an oblique incision was made in the line of the 9th or 10th intercostal space from the left anterior axillary line across the midline When the spleen was deeply placed or adherent, the lesser sac was entered through the gastrosplenic omentum to expose and ligate the splenic artery before beginning mobilisation of the spleen The spleen was brought forward and downwards by dividing from below upwards the lateral leaf of the lienorenal ligament and then the remainder of the gastrosplenic ligament containing the short gastric arteries After excision of the spleen, oozing from the raw area was reduced by suturing together the cut edges of the lienorenal and gastrosplenic ligaments, thus virtually covering the splenic bed with peritoneum If this is done, drainage is very seldom necessary, in fact it has been employed only twice An "anchored dressing" proved useful in preventing hæmatoma formation in the subcutaneous tissues

In the earlier cases in this series anæsthesia was induced with ethyl chloride and continued with open ether Latterly induction has been with intravenous thiopentone, and cyclopropane supplemented with relaxants has been used to maintain anæsthesia

Results

CASES GIVEN NO SPECIFIC TREATMENT †

No treatment other than whole-blood transfusion or hæmatinics was given to 26 patients, of whom only 3 were under 12 years of age They can be divided into two groups

The *first group* consisted of 10 patients who presented with a long history of recurring episodes of bleeding into the skin or from mucous membranes The bleeding was seldom severe and gradually subsided Throughout observation for periods as long as twelve years these patients have shown, in addition to episodes of bleeding, persistent (or in 1 case recurring) thrombocytopenia and a prolonged bleeding-time 3 have died—1 from gastrointestinal bleeding six months after the onset of symptoms, and 2 from causes unrelated to their thrombocytopenia five years and ten years after first being seen In only 1 case was there a clinical and hæmatological remission This lasted for two years, and followed a period of three years during which there had been repeated episodes of bleeding and persistent thrombocytopenia

The *second group* comprised 16 patients in whom purpura had appeared recently and without warning None had previously had a similar episode of bleeding

All 16 had crops of petechiæ in the skin and mucous membranes, 12 had persistent bleeding from the nose or gums, 5 had hæmaturia, 3 had gastrointestinal bleeding, and 5 had intracranial hæmorrhage—all females, of whom 4 died In every instance the bleeding-time was prolonged and the platelet-count below 50,000 per c mm , the capillary fragility was increased in 7 of the 8 cases in which it was estimated The 4 women who died did so within two days of admission to hospital Necropsy was performed in 3, and in each the cause of death was found to be intracranial hæmorrhage No other

---

* Present address Department of Medicine, University College, Ibadan, Nigeria

† Throughout this paper the term "specific treatment" is used to denote steroid therapy or splenectomy

University of Durham

Dr N Cauna has been appointed to a readership in anatomy in the Newcastle division

University of Birmingham

On July 17, on the occasion of the British Medical Association's conference, the honorary degree of LL D was conferred on Lieut -General Sir Alexander Drummond, director-general, Army Medical Services, the honorary degree of D SC on Dr J S Mitchell, F R S, regius professor of physic in the University of Cambridge, and the honorary degree of M D on Dr I D Grant, president of the College of General Practitioners

On July 5 the following degrees were conferred

Ch M—K D Roberts, R W Tudor

M B , Ch B—A J G Campbell, F J Fawcett, Bernard Goodhead (*second-class honours*), T R Abbott, Ada M Adams, Derek Atkinson, Ann I Ballantine, A D Barnes, Ruth Barton, Vivien E Basco, L S Bernstein, Colin Berry, J E Bewley, Kishan Singh Bhogal, H E Black, A W Burdon, Brenda M Chant, A C Cottrill, D C Crawford, J T Davies, P W Davis, D G Emery, Sylvia D Gardner, Catherine M Gay, J R Geddes, Jean M Gibbon, Selwyn Glick, M G S Golby, I A Goldman, R W Griffin, R G Harrison, Frances E Heron, M J Hoare, G B Hunt, S E O Jones, Madmood Joomye, Menigha Kemmer (in absentia), A B Lavelle, Michael Lewis, Edna J Lloyd, Wendy I McNeilly, G L Morgan, Philippa N Mourant, M G Mullan-Feroze, Kenneth Newbold, D M Nicoll, E Aigbobasimi Oni-Okpaku, C E Oxnard, Doris H Pereira, C R Phillips, P R Preston, Susan E M Richards, C J Roberts, R N Smith, D B Southall, Sheila M Statham, Margaret S Taylor, C W Thompson, F R Walford, Albert West, Nora E Wild, T H Willets, P J Witherow, D A K Woodward

Royal College of Surgeons of Edinburgh

At a meeting of the college on July 15 with Prof John Bruce, the president, in the chair, the honorary fellowship was conferred on Prof Warren H Cole and Prof Isidore S Ravdin The following were admitted to the fellowship

S M S Ashraf, D W Blair, R C Buchanan, Peter Burgess, B N Chatterjee M C Chenoy, J S G Clark, J T F de Graft-Johnson, E J England, D S Grewal, W F Hasan, Grant Kerr, G C Liggins, John McLenachan, P S Mathur, Gunaratnam Muttuthamby, K N Nambudripad, K J O'Connor, S L Paton, G R A Raad, E F Reye, M C R Solling, J W W Thomson, Mary A T Tolley, M P Trivedi, D D Verma, R E D Williams, J S Winter, N K Yong

Faculty of Ophthalmologists

The following officers have been elected for 1958–59

President, Mr L H Savin, vice-presidents, Mr E G Mackie and Prof G I Scott, hon treasurer, Mr A McKie Reid, hon secretary, Mr E F King

Royal Society of Medicine

The following have been elected honorary fellows of this society

Mr L R Broster, Dr M G Candau, Prof William B Castle, Prof Andre F Cournand, Prof Denis Denny-Brown, Prof F de G d'Allaines, Prof Herwig Hamperl, Prof G Miescher, Prof Newell Philpott, Prof Georges Portmann, and Dr F Parkes Weber

Royal Society of Health

Fellowships have been conferred by this society on the following in recognition of their public-health work

Dr William Alcock, Dr E Michael Bluestone, Dr H D Chalke, Dr Richard J Dodds, Dr Philip Drinker, Mr G L C Elliston, Dr J A Gillet, Dr I A G MacQueen, Dr W H P Minto, Dr Pin Hin Teng, and Dr W H S Wallace

Diagnostic Centre for South London

The London County Council have appointed Brigadier H L Glyn Hughes, formerly senior administrative medical officer of the South East Metropolitan Regional Hospital Board, to be medical director of the proposed diagnostic medical centre at the Queen's Road Centre, Peckham The plans for this project were described in our issue of June 7 (p 1214)

Carlsberg-Wellcome Travelling Research Fellowships

The Carlsberg Foundation (Copenhagen) and the Wellcome Trust (London) announce a second series of awards of these fellowships which they jointly instituted in 1957 The successful candidates for 1958–59 are Dr S E Jensen and Dr D A T Dick

Dr Jensen of Kommunehospitalet, Aarhus, and Aarhus University, Denmark, will work in Prof Russell Fraser's department at the Postgraduate Medical School of London on the factors affecting serum-lipoids in man, and Dr Dick, from the department of human anatomy, University of Oxford, will work with Prof H Holter at the Carlsberg Laboratory on the osmotic properties of living cells

Medical Women's International Association

Proposing the toast of this Association at the banquet in London last Monday which concluded the eighth congress, Prof Stanley Alstead, P R.F P S, spoke of the character of women as a new dimension in medicine He was one of the host of men who say of women "How illogical How charming! How right!" The Association barred discussion of religion and politics, but not of philosophy, which brings to the world a measure of tranquillity The philosophy of women embraced æsthetics, and æsthetic values constituted in themselves an international language

Dr Esther Lovejoy, first president of the Association, traced its origin partly to the work of British medical women, —including the Scottish Women's Hospitals—in the first world war She also recalled a visit she paid, at Hastings in 1904, to Elizabeth Blackwell, the first woman doctor, who qualified in the United States in 1849 Dr Aitken, as former secretary and now president, expressed her belief in the usefulness of the Association with its 29 member and 3 observer countries

Prof Robert Platt, P R.C P, proposed The Medical Profession

He had been looking at passers-by in a London street, and, having been in medicine for quite a long time, had felt that he knew about the problems of many of them How lucky doctors were to deal with this wonderful succession of people—always interesting, however exasperating they might be The profession of medicine offered greater variety than any other, and in all its branches it was far more satisfying than ever before "beware of people who say that medicine isn't what it used to be, it never was" In Britain it must be practised largely in the context of the National Health Service, which had still not got over all its initial troubles "But beware of the people in Britain who tell you that they can't practise good medicine today They are the direct descendants of those who didn't practise it yesterday" The doctor-patient relationship had changed no doubt—but in no country more than in the U S A, where the change could not be due to the N H S The most important things could not be measured by science, and Professor Alstead's description of æsthetics as an international language reminded Professor Platt of a foreign 'cellist's remark to him "For the Ravel it is not enough to have skill One must also have love" This was equally true of medicine

Dr Katharine Lloyd-Williams proposed The Guests and Overseas Visitors—from all five continents

Responding, Dr Haldorsen said that Scandinavia has 650 members of the Association, and likened the purpose of its gatherings to that of a Scottish reel—"everybody meets everybody" Dr Del Mundo spoke of the 13,000 women doctors in Japan, Australia, and the Philippines, and of the welcome awaiting the Association at its Congress in the Philippines in 1962 Prof M L Chevrel, in expressing thanks for a hospitality which had freed the visitors from care, paid particular tributes to Dr Tosoni-Dalai and Dr Aitken, late president and secretary And Dr A D Morani, in both English and Spanish, replied for The Americas

Royal Medical Benevolent Fund

The annual general meeting of this Fund will be held at 11, Chandos Street, London, W 1, on Wednesday, July 30, at 5 P M

Regional-board Appointments

Dr H M C Macaulay retires on July 31 from the post of senior administrative medical officer to the North West Metropolitan Regional Hospital Board, and he will be succeeded by Dr F J Fowler Dr Fowler is at present deputy senior administrative medical officer to the North East Metropolitan Regional Hospital Board and he will be succeeded by Dr T A Ramsay

Dr Fowler, who is 46 years of age, graduated M.B from the University of Birmingham in 1935 After holding house appointments in Birmingham, he became in 1938 senior assistant medical officer at Derby City Hospital During the late war he served with the R A.M C in France, North Africa, and Algiers, finally serving, with the rank of colonel, as A D M S (administration) at Allied Force Headquarters On demobilisation in 1945 he was sent under the postgraduate training scheme to Hallam Hospital, West Bromwich, to work under Dr J H Sheldon In 1948 Dr Fowler was appointed assistant senior medical officer to the Oxford R H B He took up his present appointment in 1951 has now lasted for a year No improvement was observed in 2 patients (nos 1, 2) while they were receiving corticotrophin, but twenty days after stopping treatment there was a spontaneous remission. 3 patients (nos 9, 10, 16) obtained no benefit from steroid therapy and were submitted to splenectomy Of the other 8 patients, 1 (no 4) was given corticotrophin 30 mg daily for seventeen days, and thirteen days later experienced a complete remission, and 7 were treated with cortisone or prednisolone for three weeks or more 3 (nos 11, 12, 17) of these 7 patients had a complete remission starting at the end of the course of treatment and have remained well since, but 4 (nos 13, 14, 18, 19) did not benefit and were submitted to splenectomy

This group of short-history cases is a small one, for the condition is uncommon, and several of the patients have been treated with doses and for periods of time which would be considered inadequate by modern standards (Sturgis 1951) Nevertheless, in this group response to steroid therapy was not related either to dosage or to the duration of treatment, and in this respect our observations confirm those on idiopathic thrombocytopenic purpura reported by the Medical Research Council Hæmatology Panel (1953)

12 patients who were treated before 1949 and therefore did not receive steroids, and 7 who had failed to benefit from them, were submitted to splenectomy within a hundred days of the onset of symptoms (table II)

Operation was followed by a rise in platelet-count in 15 patients, of whom 13 have remained in complete remission for as long as they have been followed up and 2 (nos 4 and 15, table II) relapsed within three months 3 patients (nos 5, 7, 9), on whom operation was performed as an emergency because of the severity of their condition, received little or no immediate benefit, but started a complete remission between ten and forty-nine days later In 1 of these (no 7, table II) the platelet-count fell and symptoms recurred five weeks after splenectomy, but he improved rapidly on a small dose of prednisolone The remaining patient (no 19) did not show any rise in platelet-count and died from a cerebral hæmorrhage some six years after splenectomy 5 of the 7 patients in this group who failed to respond to steroids benefited clinically and hæmatologically from splenectomy

17 short-history cases have been observed for a year or more after splenectomy Repeated observations over periods from a year up to twenty-three years after operation indicate that a good clinical and hæmatological remission has been obtained consistently in at least 75% of short-history cases (table V)

Long-history Cases

36 patients received specific therapy more than a hundred days after the onset of symptoms

Corticotrophin, cortisone, or prednisolone was given to 23 patients (table III) In 3 cases (nos 1, 2, 3) this has been the only treatment given the other 20 patients have also been treated by splenectomy Steroid therapy was given to 11 patients only before operation, to 6 only after splenectomy had failed to relieve the condition, and to 3 both before and after operation

The results of steroid treatment, as judged by relief of symptoms and a platelet-count above 150,000 per c mm, were similar whether the patient received the steroids

TABLE III—LONG-HISTORY CASES TREATED WITH CORTICOTROPHIN CORTISONE, OR PREDNISOLONE

Patient	Age	Sex	Duration of symptoms (yr)	Treatment			Day platelets rose above 150,000 per c.mm.	Duration of platelet rise (days)	Length of follow-up (yr)	Progress
				Drug	Dose (mg)	Days given				
Cases treated with steroids alone										
1	33	F	3	Cortisone	100	12	7	4	5	Remission started 3 years later
2	26	M	20	Cortisone	100	9	—	—	5	Well when seen 5 years later
3	45	F	45	Corticotrophin	100	10				
				Cortisone	200	10	—	—	4	No improvement.
Cases treated with steroids followed by splenectomy										
4	38	F	12	Cortisone	100	12	—	—	4	Well.
5	29	F	2	Cortisone	100	15				
				Corticotrophin	160	10	—	—	5	Well.
6	40	F	5	Corticotrophin	100	14	10	4	—	3 months interval.
				Cortisone	100	21	9	11	—	1 month interval.
				Cortisone	100	10	9	—	6	Well.
7	72	F	6	Cortisone	150	22	—	—	3	No improvement.
8	66	F	1/12	Cortisone	200	10	8	2	1/2	Well
9	57	F	2	Cortisone	200	10	7	3	3	Well
10	16	F	3	Cortisone	300	10	—	—	2	Well
11	50	F	1/12	Cortisone	300	22	10	12	1	Well.
12	14	F	6/12	Cortisone	200	13	15	60	3	Splenectomy 1 year later
					300	15				
13	11	F	6	Cortisone	200	7	6			
					50	8	—	9	—	1 week interval
				Prednisolone	15	120	14	44	—	2 months interval
				Prednisolone	45	17	8	—	1/2	Well
14	28	M	12	Prednisolone	50	28	—	—	1/2	Well.
Cases treated with steroids after splenectomy only										
15	22	F	*1	Corticotrophin	100	10	—	—	6	No improvement.
16	30	F	*5	Cortisone	200	10	3	7	5	Purpura persists
17	36	F	*12	Prednisolone	50	21	12	39	1/2	Purpura persists
18	36	M	*10	Prednisolone	60	12	10	10	—	Course given for dental extractions
19	33	F	*1/12	Cortisone	100	10	—	—		No change in symptoms at any time.
					75	100			2	
20	38	M	*7	Cortisone	300	21				
					200	30	—	—	—	5 months interval.
				Prednisolone	50	21				
					40	5				
					15	200	—	—	1	No change in symptoms at any time.
Cases treated with steroids before and after splenectomy										
21	5	F	3	Cortisone	50	17	—	—	—	Well 3 years, then relapse
			*4	Prednisolone	50	16	6	46	4	Purpura persists
					10	270				
22	65	F	4	Cortisone	200	21				
					100	28	—	—	—	No improvement.
			*1/12	Prednisolone	60	22				
					20	39				
					10	360	—	—	1	No improvement
23	31	F	15	Cortisone	200	21	16	4	—	No improvement.
			*1	Cortisone	300	21	11	10	—	No improvement.
					50	100	—	—	1	1 year interval
			*2	Prednisolone	60	22	4	9	1/2	No improvement.

* Indicates that splenectomy had been performed this period of time before steroid therapy began.

TABLE I—SHORT-HISTORY CASES TREATED WITH CORTICOTROPHIN OR CORTICOIDS

Patient	Age	Sex	Duration of symptoms (days)	Treatment			Day platelets rose above 150,000 per c.mm.	Splenectomy	Length of follow-up (yr)	Progress
				Drug	Dose (mg)	Days given				
1	55	M	47	Corticotrophin	100	10	30		6	Well †
2	20	F	3	Corticotrophin	100	10	30		6	Well
3	32	M	30	Corticotrophin	100	3	3		6	Well
4	3	F	2	Corticotrophin	30	17	30		1	Well
5	33	M	2	Cortisone	100	4	4		5	Well
6	22	F	1	Cortisone	200	10	6		1/12	Well
7	59	M	3	Cortisone	300	8	4		3	Well
8	6	F	12	Cortisone	100	10	8		1	Relapsed immediately, but 30 days later started a spontaneous remission. Remains well
9	45	F	1	Cortisone	200	8	—	Yes	1	Cerebral hæmorrhage No change in symptoms until 49 days after splenectomy when platelets rose to and have remained at normal levels
10	26	M	21	Cortisone	200	10	—	Yes	1	Well
11	12	M	35	Cortisone	250	21	20		1	Well
12	29	M	1	Cortisone	300	21	21		1/12	Remains well on prednisolone 5 mg daily
13	31	F	6	Cortisone	200	20	—	Yes	3	Well
14	56	F	56	Cortisone	200	21	—	Yes	4	Well
15	69	F	21	Prednisolone	50	10	6		1	Well
16	40	M	4	Prednisolone	50	10	—	Yes	6/12	Severe hæmorrhage continued. Splenectomy followed 10 days later by [illegible] platelets Relapsed after 5 weeks
			*1	Prednisolone	20	12	10			Remission with steroids Now well.
17	14	M	2	Prednisolone	50	28	20		6/12	Well
18	62	F	7	Prednisolone	50	21	—	Yes	6/12	Melæna on 28th day Splenectomy Well
19	40	F	40	Prednisolone	60	24	—	Yes	1	Well

* 5 weeks after splenectomy

† In all tables the following terms are used
Well —Patient examined free of symptoms and platelet-count within normal limits
Presumed well —Patient reported by letter free of symptoms

disease was present The distinguishing feature of the other 12 cases was a spontaneous and apparently permanent recovery The hæmorrhagic phenomena stopped within fourteen days of admission, and concomitantly the platelet-count began to rise, becoming normal, in every case, within a hundred days of the onset of symptoms There has been no recurrence, and the patients have remained well for as long as they were followed up, which in 5 cases was for more than nine years

The existence of this second form of thrombocytopenic purpura, sudden in onset and short in duration, suggested to us the arbitrary division of our patients who were treated with corticotrophin, corticoids, or splenectomy, into (1) those in whom the onset was less than a hundred days before treatment started, and in whom, therefore, the possibility of spontaneous remission was still present (hereafter referred to as short-history cases), and (2) those with a history of more than a hundred days, in whom the possibility of spontaneous remission was slight (long-history cases) Hirsch and Dameshek (1951) selected a period of a hundred and twenty days, whereas Wintrobe et al (1937) thought that spontaneous remission was common before fifty days had elapsed but unusual thereafter Support is lent to our choice of a hundred days as the arbitrary dividing-line by the fact that 3 patients in this series have had between them 7 children who were born with thrombocytopenia and purpura and recovered spontaneously at varying intervals up to ninety days after birth A similar duration for this type of neonatal thrombocytopenia is recorded by Epstein et al (1950), Neville and Masterman (1954), and Schoen et al (1956)

It should be emphasised that the only factor taken into consideration in placing a patient in one or other of these two groups is the duration of *symptoms* before treatment was started The number or severity of hæmorrhagic manifestations, the degree of thrombocytopenia, and the prolongation of the bleeding-time have not influenced the classification

CASES GIVEN SPECIFIC TREATMENT

Short-history Cases

In 31 patients specific treatment was begun less than a hundred days from the onset of symptoms 19 patients were treated with corticotrophin (A C T H), cortisone, or prednisolone (see tables I and VI)

In 11 cases the duration of treatment was ten days or less There was complete remission of symptoms and a rise in platelet-count *to above 150,000 per c mm, which persisted after* treatment was stopped, in 5 of these patients (nos 3, 5, 6, 7, and 15, table I) In 1 patient (no 8) there was a temporary improvement, followed by a relapse when the drug was withdrawn and thirty days later by a spontaneous remission which

TABLE II—SHORT-HISTORY CASES TREATED BY SPLENECTOMY

Patient	Age	Sex	Duration of symptoms before splenectomy (days)	Previous treatment	Day platelets rose above 150,000 per c mm	Length of follow-up (yr)	Progress
1	18	M	2	—	1	8	Well.
2	31	M	4	—	1	12	Well 1 year No purpura Died from pulmonary tuberculosis
3	47	F	4	—	1	1	Well
4	27	M	7	—	1	3	4 weeks after operation platelet-count fell to 50,000 per c.mm. Remained low but symptoms improved.
5	45	F	9	Cortisone	49	1	No immediate response. Now well.
6	11	F	10	—	1	23	Well
7	40	M	14	Prednisolone	10	1/2	Delayed response Relapsed 5 weeks after operation Now well.
8	52	F	17	—	2	7	Well
9	54	F	20	—	23	9	No immediate response Now well
10	31	F	26	Cortisone	1	3	Well
11	62	F	28	Cortisone	1	1/2	Well
12	26	M	31	Cortisone	5*	1	Well
13	34	F	31	—	1	17	Well
14	30	F	40	—	1	9	Well
15	50	F	42	—	3*	15	Except for 2 periods of 2 years each platelets remained below 150 000 per c.mm
16	56	F	77	Cortisone	10*	4	Well
17	28	F	84	Cortisone	1	2	Well
18	19	F	84	—	8*	3	Well
19	55	F	91	—	—	6	Platelets always less than 50,000 per c.mm. Died from cerebral hæmorrhage

* This was the first day after operation on which platelets were counted.

observed to run a more chronic course (group B, table VII), two features emerge.

First, in group A the sex-incidence was 15 females and 13 males (1·15 to 1), whereas in group B it was 38 females and 11 males (3·5 to 1).

Secondly, the onset of symptoms in the cases with a short history was evenly spread throughout the age range, but in the group with a long history it was before the age of 30 in 37 of the 49 cases; in 7 of the remainder, all women, the onset was in the sixth decade.

For these observed differences in sex and age incidence in our two arbitrary groups of short-history and long-history cases, we can offer no explanation and we shall draw no conclusions from them.

Idiopathic thrombocytopenic purpura may present without previous warning as an episode of mild or moderate bleeding into the skin and from mucous membranes or as an illness which is serious either because of the degree of blood-loss or, as in intracranial hæmorrhage, because the site of bleeding is particularly dangerous. It is recognised that even when no specific treatment is given, spontaneous recovery can occur. However, serious symptoms may supervene even in mild cases at any time and especially in the first few days of the disease. 4 of our patients had intracranial hæmorrhage and died within two days of first being seen. The results of steroid therapy in our short-history cases suggest that these drugs do no more than facilitate the natural tendency of this disease to spontaneous remission and possibly accelerate its onset. Evidence from our cases about the place of splenectomy in the severely ill patient with a short history is equivocal.

3 patients (2 of whom were receiving cortisone at the time) were submitted to operation because of intracranial hæmorrhage or hæmatemesis. In none was there any immediate improvement, and 2 continued to bleed considerably, until all 3 recovered apparently spontaneously between ten and forty-nine days after operation. Another patient, in whom a diagnosis of intracranial hæmorrhage was made because of the sudden onset of dysarthria and monoplegia, was not submitted to operation and made a good recovery within three weeks.

On the other hand, there is convincing evidence of the beneficial effect of splenectomy once the acute hæmorrhagic phase has passed (tables II and V). Symptoms were immediately relieved, the bleeding-time was shortened and the platelet-count rose in 13 of the 14 patients of whom full records were kept; improvement persisted in at least 75% of cases followed up for more than twelve years after operation.

Our results suggest that the initial management of the patient with a short history of purpura should be blood-transfusion to replace any serious blood-loss and administration of cortisone (75 mg. every six hours) or prednisolone (15 mg. every six hours) for three weeks. If the platelet-count rises during this time, there is a very good chance that it will be maintained. If there is no improvement within three weeks, splenectomy should be performed in the expectation that at this time it will be followed by a good result in 75% of cases. We can adduce no evidence to show that the patient in the acute hæmorrhagic phase is benefited by splenectomy.

Patients with a long history of relapsing purpura should also be given a three-week course of steroid therapy. About half of all patients (table VI) improved during or shortly after treatment, but it is evidently exceptional for any such remission to last for more than sixty days. Therefore, it seems that all these patients should be submitted to splenectomy either during the steroid-induced remission or as soon as it is apparent that the treatment has failed to influence the platelet-count. However, when a remission does occur it may be justifiable to defer operation in milder cases, especially if it is a response to the first course of steroid treatment. Delay in these circumstances is probably harmless, provided the patient is able to report frequently for hæmatological examination so that the impending relapse can be anticipated and a further course of steroid therapy given as a preliminary to splenectomy. The chances of a permanent remission following splenectomy in this group of our patients, though less than in those with a short history, were still in the region of 50% up to twenty years after operation (table V).

Lundy (1953) has drawn attention to the danger of circulatory collapse during the induction of anæsthesia, and up to seventy-two hours after operation, in patients who have been treated with corticoids over long periods or who have received reduced amounts immediately before operation. No such collapse has been observed in our patients, but it is important to keep the patient fully under the influence of these drugs for seventy-two hours after splenectomy. Thereafter the dose can be reduced over a period of seven to ten days, but may have to be raised again to the initial high level should any complications arise after operation. In our series there have been no deaths in hospital after splenectomy, and com-

TABLE VI—EFFECT OF CORTICOTROPHIN, CORTISONE AND PREDNISOLONE

Drug	Dose (mg. per day)	Short-history cases			Long-history cases		
		Sustained remission	Temporary remission	No remission	Sustained remission	Temporary remission	No remission
Corticotrophin	30			1*			
	100	1		2*		1	3
		(4)	(1)	(3)		(6)	(4)
Cortisone	50–150	1	1*			2	6
		(2)		(2)		(3)	(2)
	200–300	4		4		7	3
		(2)		(1)		(1)	(1)
Prednisolone	15					1	
	45–60	2		3		4	3
Total		8 (8)	1 (1)	10 (6)	0 (0)	12 (10)	11 (7)

Figures in parentheses refer to cases reported by other workers (see text).
* These 4 patients subsequently had a spontaneous remission.

TABLE VII—93 CASES OF IDIOPATHIC THROMBOCYTOPENIA DIVIDED INTO GROUPS TO SHOW AGE AND SEX INCIDENCE

Age at first symptom (yr.)		0–9	10–19	20–29	30–39	40–49	50–59	60–69	70–79	Total
Short-history group (A)	Male	1	4	2	2	1	3	0	0	13
	Female	3	2	2	2	2	1	2	1	15
Long-history group (B)	Male	2	4	4	1	0	0	0	0	11
	Female	9	8	10	1	1	7	1	1	38
Unclassified because splenectomy was performed during first 100 days of disease	Male	0	1	1	1	1	0	0	0	4
	Female	0	1	2	2	2	3	2	0	12
Totals	Male	3	9	7	4	2	3	0	0	28
	Female	12	11	14	5	5	11	5	2	65

Group A comprises 28 patients: 16 who had no specific treatment, 12 who recovered within 100 days of onset and had received steroid therapy.
Group B comprises 49 patients: 10 who had no specific treatment, 33 who had splenectomy more than 100 days after onset, 3 who had splenectomy less than 100 days after onset and subsequently relapsed, 3 who had steroid therapy only more than 100 days after onset.

before splenectomy was performed or after it had failed (table III)

Thus 17 patients were treated with steroids before operation, with 8 remissions, and 9 after operation, with 5 remissions However, there is some evidence that higher doses of cortisone (over 200 mg per day) and of prednisolone (over 45 mg per day) were more effective A rise in the platelet-count and improvement in the clinical condition were observed during only 3 of 9 courses of treatment in which doses lower than this were given, whereas with the higher dose remissions were seen 11 times out of 18 In every instance both before and after splenectomy, the remission began within sixteen days of starting treatment, but in none did it last longer than sixty days On 7 occasions (nos 8, 9, 11, 16, and 23, table III) the relapse began while the patient was still receiving a large dose of the drug (either cortisone 200 mg per day or prednisolone 50 mg per day) 2 patients (*nos 21, 23*), who had responded to a large dose with a complete remission, were given long-term treatment with reduced doses, but both relapsed with symptoms comparable in severity to those before treatment was started. 3 other patients (nos 19, 20, 22), given long-term treatment, failed to benefit in any way

TABLE IV—LONG-HISTORY CASES TREATED BY SPLENECTOMY

Patient	Sex	Age at onset (yr)	Age at diagnosis (yr)	Previous treatment	Age at splenectomy	Length of follow-up (yr)	Progress
1	F	0–1	14	—	14	29	Remitting course Platelets 70,000 – 230,000 Symptoms improved.
2	M	0–1	5	—	5	1½	Died cerebral hæmorrhage.
3	F	0–1	20	—	20	5	Menorrhagia severe 2 of 3 children had thrombocytopenia
4	F	1	20	—	24	12	Menorrhagia severe
5	F	2	5	Cortisone	5	4	Well 3 years, then relapse
6	M	4	13	—	17	10	Well Killed on active service
7	M	5	5	—	6	9	Well
8	F	5	10	Cortisone Prednisolone	11	½	Well
9	F	6	9	—	14	9	Well 1 of 2 children had thrombocytopenia
10	F	11	11	—	13	5	Well
11	F	12	12	—	14	9	Well 2 years and reported well till died suddenly in relapse.
12	F	14	15	Cortisone	15	2	Well
13	F	16	16	Cortisone	17	2	Presumed well
14	F	16	25	—	25	10	Symptoms unchanged
15	F	16	30	Cortisone	31	2	Relapse after 2 weeks Severe menorrhagia continues
16	M	16	28	Prednisolone	28	½	Well
17	F	18	19	—	19	24	Well
18	F	21	22	—	24	23	Presumed well 7 years Relapse with severe *symptoms for past 16 years*
19	F	23	24	—	24	10	Well
20	F	25	25	—	26	3	Well until death from disseminated sclerosis
21	F	26	38	Cortisone	38	4	Relapse after 6 weeks Platelets below 50,000 per c.mm thereafter, but symptoms reported less
22	M	26	28	—	28	24	Known well 3 years Presumed well 21 years
23	F	27	29	Cortisone	30	5	Well
24	M	28	32	—	32	8	Severe symptoms *for* past year
25	F	30	31	—	31	12	Remitting course with platelets from 30,000–280,000 per c.mm.
26	M	33	35	—	38	11	Well
27	F	35	35	Cortisone Corticotrophin	40	6	Well
28	F	49	50	Cortisone	50	1	Well
29	F	52	53	—	53	2	Unchanged *Severe symptoms*
30	F	55	57	Cortisone	57	3	Well
31	F	61	61	Cortisone	65	2	Unchanged
32	F	66	66	Cortisone	66	½	Well
33	F	66	68	Cortisone	72	3	Relapse after 10 days

TABLE V—RESULT AT INTERVALS AFTER SPLENECTOMY

Period of observation (yr)	Short-history cases					Long-history cases				
	No	Traced	Well	Presumed well	% success	No	Traced	Well	Presumed well	% success
1	17	17	14	—	83	30	29	17	2	65
4	10	10	6	2	80	20	18	8	3	61
8	8	8	5	1	75	14	14	5	2	50
12	4	4	2	1	75	6	6	1	1	33
20	1	—	1	—	—	4	4	1	1	50

Splenectomy was performed in 33 patients with a long history of purpura—as the only specific treatment in 19 and after the administration of steroids in 14 (table IV) Follow up of these patients has shown that a year after splenectomy 19 of 29 patients (65%) were symptom-free and had platelet-counts and bleeding-times within the normal range, and that the proportion of those completely relieved declined to 61% at four years and to 50% or under between eight and twenty years after operation (table V)

In 22 patients the platelet-count was recorded within the first four days after operation It was within the normal range within twenty-four hours of splenectomy in 15 and within forty-eight hours in a further 2 The other 5 patients still showed thrombocytopenia on the fourth day, and in none of them was a normal platelet-count ever observed over periods of from one to twelve years after operation

Discussion

The results of steroid therapy are summarised in table VI

Almost half the patients with a short history of purpura (8 of 19) developed, during the course of treatment, a complete remission which was maintained after treatment was stopped In the group of patients with a longer history again about half (12 of 23) showed distinct improvement, but this was never maintained for more than sixty days This seemed such an important contrast that confirmation was sought in the reported experience of other workers (Bethell et al 1951, Fallon et al 1952, Jacobson and Sohier 1952, Meyers et al 1952, Stefanini et al 1952, Wilson and Eismann 1952, Adamson et al 1953, Greene et al 1953) Sufficient details to allow analysis were obtained for 32 patients (table VI) The results closely resemble those in our series In a further communication Stefanini (1955) said that permanent remission following steroid therapy was common among patients with a short history, but exceptional among those with a longer history of purpura The inference to be drawn from these observations appears to be that permanent remissions are not directly due to treatment with steroids, but may in some instances be hastened by it If this inference is accepted, it follows that the 12 patients among our short-history cases who entered a permanent remission during or shortly after treatment with corticotrophin or steroids (tables I and V), were examples of the self-limiting type of the disease, and in this respect are comparable with the 12 patients with a short history who recovered without steroid therapy or splenectomy

If these two groups of 12 patients, and the 4 who died without treatment within a short time of the onset of purpura, are considered together (group A, table VII) and compared with the 49 in whom the condition was nclair et al (1948a), repeating similar work with curate radiographic control of the position of the needle oint, suggested that it was the medial branch of the osterior primary division of the sensory root that was eing stimulated

There is also controversy about the more general neural mechanisms involved in referred pain The view put forward by several workers (e g Harman 1948) that reference is in part a cerebral event can hardly be denied, but this must play its part *after* more distal mechanisms have operated, and about these there is still conflict

One view (Mackenzie 1909) was that an "irritable focus" was produced at segmental level in the cord, with the result that sensation of pain from any part of the periphery of that segment spread to the central connections of all parts In its modern guise this has become the concept of a common sensory pool of neurones fed from skin, deep structures, and viscera in the appropriate segment (Hinsey and Phillips 1940, inclair et al. 1948b)

The other view considers that reference takes place at the periphery by misinterpretation of impulses coming up an axon which is branched and supplies both deep structures and skin, or by antidromic impulses passing down such a branched axon and producing chemical changes at the site of referred pain, or alternatively by a combination of both these mechanisms (Lewis 1942, Sinclair et al 1948b)

The physiological evidence on these two views has been assessed by Gordon (1975) Our observations may be relevant to, and derive added interest from, current theories of the mechanism of referred pain

Methods and Material

When 0 3 ml of 6% saline solution is injected as far as possible exactly into the midline of the back in the region of the interspinous ligaments at a depth of 2 or 3 cm, the immediate effect is stinging burning pain around the site of injection This is usually bilateral but may be more on one side than the other or entirely unilateral It subsides in one or two minutes, and, as it is subsiding, or after it has largely cleared, an unpleasant dull deep aching pain is experienced in the peripheral part of the segment injected and is sometimes accompanied by palpable spasm of the muscles of the segment Thus, for instance, when injections are made below the L5 spinous process, pain may be experienced in the shin, and spasm of the anterior tibial muscle may be felt The pain, although felt to be deep, can usually be clearly outlined by an intelligent witness

Sometimes accompanying this deep pain, and sometimes more delayed, a skin tenderness may develop, again mainly in the peripheral parts of the segment involved This hyperalgesia can become very severe and is similar to clinical hyperpathia in the skin area involved even the lightest touch may produce severe pain, ill defined in extent and hard to describe except as very unpleasant, but the raised threshold with subsequent overaction generally defined as hyperpathia is not in evidence

While this sensation lasts, the skin is carefully guarded from any contact, much as it is in causalgia This hyperalgesic effect is in our experience much less common than the others It may develop later than the deep pain and does not usually last longer than half an hour, whereas deep pain, described as vague muscle tenderness or a bruised feeling, may last as long as twenty-four hours or so after injection

All these effects may be unilateral or bilateral In our experience they are more commonly bilateral, especially in the cervical and thoracic regions, provided that the injection is made exactly in the midline Though some of these referred effects follow in most cases, occasionally none of them occurs and it must be emphasised that the only almost invariable accompaniment of the injection of saline solution is the local stinging pain

If, instead of 6% saline solution, 2% procaine is injected in the same way, there is occasionally produced a numb cold feeling referred mainly to the periphery of the skin of the appropriate segment There is a feeling also that the muscles underlying it are not responding with normal facility While this effect lasts, the sensory response to both cotton-wool and pinprick in the area changes both stimuli are considered to be less clear or less sharp It has been impossible, however, to test

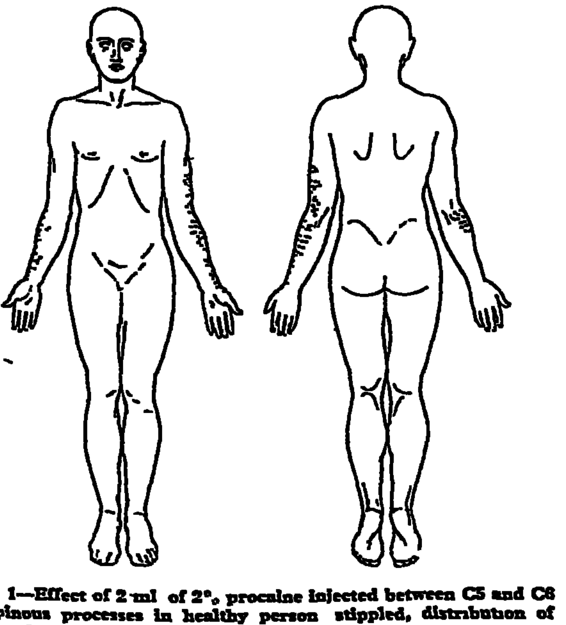

Fig 1—Effect of 2 ml of 2% procaine injected between C5 and C6 spinous processes in healthy person stippled, distribution of numb cold feeling

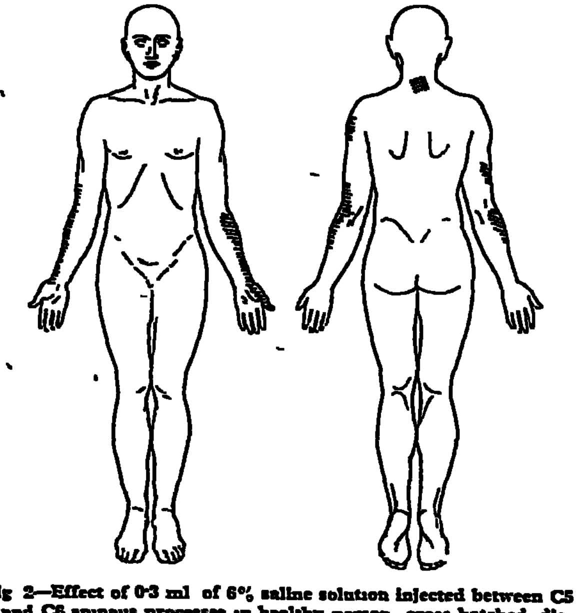

Fig 2—Effect of 0·3 ml of 6% saline solution injected between C5 and C6 spinous processes in healthy person cross-hatched, distribution of immediate stinging pain, hatched, distribution of deep aching pain

plications have been few and in general have been those that may follow any major upper abdominal operation

1 patient, who was drained at the time of the splenectomy, developed a left subphrenic abscess, which needed surgical treatment on the sixteenth day after operation She made a good recovery and was discharged home two months later In 3 cases subcutaneous hæmatomata led to partial separation of the wound edges, but in only 1 of these was further operation needed

Thus, in good surgical circumstances and provided the diagnosis of idiopathic thrombocytopenic purpura has been established by all means including the presence of megakaryocytes in bone-marrow smears, splenectomy is a safe operation and should not be unduly delayed However, patients with very mild symptoms, particularly if elderly, may remain relatively undisturbed by their thrombocytopenia for a long time 10 such patients have been followed up for periods of from three to ten years, and none of them has had symptoms sufficient to warrant admission to hospital, let alone to justify splenectomy In such cases a watching brief may be permissible

The management of the patient who continues to have severe symptoms after splenectomy is difficult Long-continued treatment with cortisone (75–100 mg per day) or prednisolone (10–15 mg per day) was given to 5 such patients in this series (and in higher doses to another operated on more recently) without any significant improvement in platelet-counts or in the severity of symptoms In contrast to these results, 2 of 4 patients who had failed to respond to splenectomy were treated by the Medical Research Council Hæmatology Panel (1955) with cortisone (50–100 mg daily) for more than six months and were maintained in remission for that time The details of these cases were not given and it may be that the 2 who were maintained had short histories and might, therefore, have remained well once a remission had been obtained—as did our case 16 (table I) Among the other reports in the literature we have failed to find an example of a patient with a *long history* of purpura having had a steroid-induced remission lasting more than two months (table VI)

The results of steroid therapy in our patients who relapsed after splenectomy (table III) suggest that if there is going to be improvement it will be evident within three or four weeks of the start of treatment, and will almost certainly not be maintained for much more than two months If the platelet-count has not risen within this time, it is unlikely to do so with further continuous treatment, no matter how intense or how long-continued It is better to stop treatment, accepting any minor clinical improvement that may have occurred, and to start another course should bleeding recur Whenever a minor operation or dental extraction is necessary in a patient with a persistently low platelet-count after splenectomy, it should be covered by a course of prednisolone starting four or five days before operation and lasting not less than ten days

Summary

93 cases of idiopathic thrombocytopenic purpura are reviewed

The progress of 26 patients who received neither steroid therapy nor splenectomy led us to classify the remaining 67 into two groups—namely, those who had a history of less than a hundred days from the onset of symptoms to the start of treatment (short-history cases) and those in whom this interval was more than a hundred days (long-history cases)

The response to treatment in these two groups described, and important differences in regard to prognosis and treatment are noted and discussed Short-history cases tended to remit spontaneously, and the onset of such a remission appeared to be hastened by steroid therapy Splenectomy was followed by good results in more than 75% of short-history cases in which a remission, spontaneous or induced, had not occurred. In long-history cases the chances of a spontaneous remission or of a lasting remission from steroid therapy are very small Splenectomy was followed by a good result in some 50–60% of long-history cases

Recommendations for the management of patients with idiopathic thrombocytopenic purpura are made

We wish to express our gratitude to all those physicians and surgeons in Edinburgh who have referred to us patients with purpura or have allowed us to include patients on whom they have operated—in particular to Sir James Learmonth, in whose charge most of the splenectomies were performed The help of our colleagues in the blood clinic and of Miss Sheila T Lindsay, B SC, who was responsible for most of the blood-counts, is also gratefully acknowledged

THE injection of hypertonic saline solution into the deep midline structures of the back produces both local and referred pain (Kellgren 1939, Lewis and Kellgren 1939) We have found this method of inducing referred pain useful both in investigating and treating cases of spontaneous pain of doubtful ætiology and in extending the clinical examination of loss of sensation of pain in certain known lesions of the central nervous system We report and discuss briefly here some observations made in such cases

Lewis and Kellgren (1939) considered they were stimulating the interspinous ligaments by their injections, but ensory loss is present from a cord lesion, it is still possible o get referred sensation by injecting hypertonic saline olution, but the sensation is modified

Case 2—A man, aged 22, dived into shallow water and ustained a crush fracture of the C5 vertebra After the immediate phase of spinal concussion had subsided, he had a Brown-Sequard syndrome with paresis of his left arm and leg and sensory loss to pinprick and temperature at the C6 segment and below on the right side There was also some posterior-column loss on the left paretic side The condition had been static for some years when he was examined

Injection of saline solution—Fig 3 shows the effect of injecting saline solution into the C7–D1 interspace There was immediate pain in the cross-hatched area only to the left of the injection site Some minutes later a typical dull aching pain developed in the hatched area in his left arm and hand Shortly afterwards, however, his right forearm experienced, in the dotted area which was within the area of spinothalamic loss, a tingling feeling which was neither painful nor unpleasant and was described as "like a tuning-fork" On another occasion he was given an injection of saline solution in the D6–D7 interspace The effect is shown in fig 4 Again the immediate stinging pain was felt just to the left of the injection site Then, during the next two or three minutes, there was a slow build-up of a bilateral unpleasant dull ache, felt as deeply placed and described as like being winded No skin hyperalgesia developed on either side The referred sensation was clearly felt on both sides, and even on direct questioning the patient denied any difference in intensity on the two sides

When the spinal cord is the site of a local lesion, this may also affect the site of reference of some of the sensations induced by the dorsal midline injection of saline solution, as case 3 illustrates Some of the effects noted in this case, although quite definite, are rare in our experience, we have only been able to produce them in one other case of spinal-cord lesion, though we have tried in several

Case 3—A boy, aged 20, was referred by the Army Medical Services because of difficulty in walking long distances

On examination he had a very slight spastic paraparesis There was a sensory level to light touch and pinprick at the D9 segment but no absolute sensory loss He had some degree of kyphus at the D7–D9 vertebræ. Laminectomy later showed a cord obviously stretched over the kyphus with some arachnoid adhesions at this level

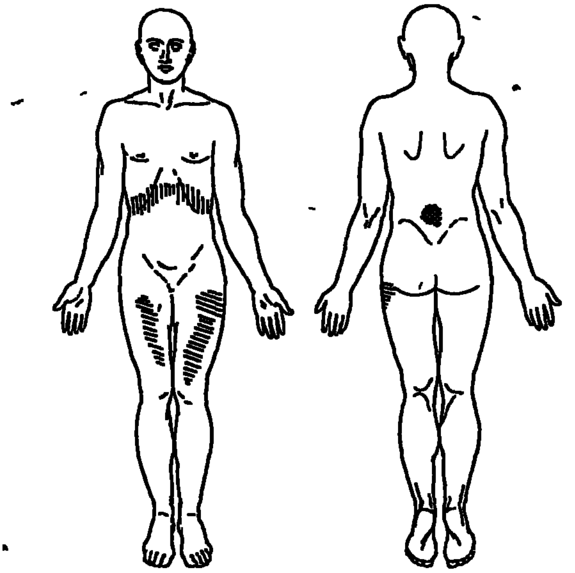

Fig 5—Effect of 0 3 ml of 6% saline solution injected between L3 and L4 spinous processes in case 3, with cord lesion and D9 sensory level cross-hatching, immediate stinging pain; transversely hatched, deep aching pain; vertically hatched, acute skin hyperalgesia

Injection of saline solution—The patient was tested with hypertonic saline solution some days before the operation Fig 5 shows the effects of an injection at the L3–L4 interspace There was immediate stinging pain in the cross-hatched area on both sides of the injection site As this subsided, a typical dull aching pain developed in the anterior parts of the thighs (hatched areas) There was no skin tenderness or hyperalgesia It was thought that the left quadriceps showed slight spasm to palpation The referred pain was more severe on this side than on the right The acute effect subsided in about ten minutes, and there remained only a slight feeling of muscle tenderness on the left However, about three-quarters of an hour after the injection there developed quite rapidly over two or three minutes severe hyperalgesia and tenderness of the skin over the epigastric region and lower rib margins (vertical hatching) So intense was this that the patient could not bear his pyjamas to touch the area and carefully held his clothes away from it, flinching at the slightest touch This intense effect lasted about ten to fifteen minutes and then gradually subsided Thirty minutes after the onset of the pain his skin was still hyperæsthetic to light touch, and pinprick felt unduly sharp, but these sensations were no longer unendurable, and he could button his jacket and tie his pyjama cord in comfort

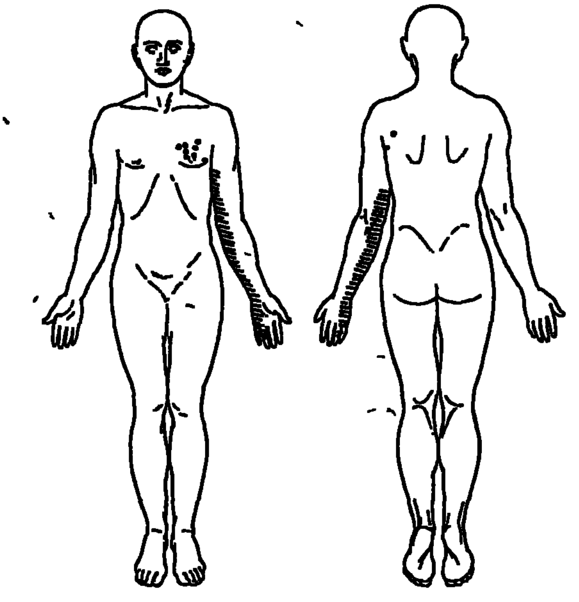

Fig 6—Case 4 with herpes-zoster scarring (small circles) and effort angina (hatched)

Case 4 illustrates that pain referred from a superficial focus in one segment may apparently summate with other potentially painful impulses not necessarily in the same segment The result may be pain referred to more than one segment This type of observation is not new Case 4 is of interest as illustrating some interconnection between three separate sources—pain of superficial origin, pain from deep somatic structures, and pain of supposedly visceral origin

Case 4—A woman, aged 64, had ten months' history of persistent post-herpetic pain After some prodromal symptoms a mainly D3–D4 herpes zoster had developed on the left side Vesication was slight and mainly on the anterior part of the body There was no secondary infection, and subsequent scarring was slight Nevertheless since the onset the patient quantitatively to determine whether sensory threshold has risen or not This effect is far less constant than that of the saline solution, and 1–2 ml of procaine has to be used to produce it

Fig 1 shows the effect of such a procaine injection in a healthy volunteer The effect was quite striking Although the volunteer had not been instructed in what he might feel he could outline readily the areas of sensory change produced The effect was clearcut only for fifteen minutes or so

Fig 2 shows the effect, on a different occasion in the same volunteer, of injecting 6% saline solution into the same area No skin hyperalgesia was produced, the hatched area representing the reference of deep aching pain Although roughly similar, the areas are neither strictly congruous nor entirely symmetrical Such variations and asymmetries are usual both with saline and with procaine injections

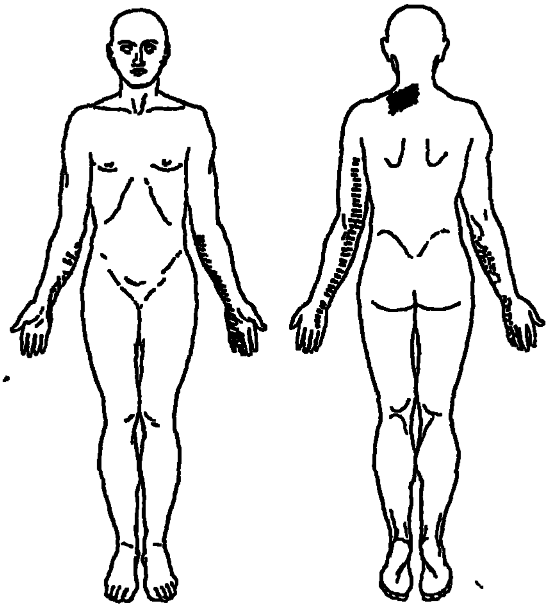

Fig 3—Effect of 0 3 ml of 6% saline solution injected between C7 and D1 spinous processes in case 2 with right spinothalamic loss below C8: cross-hatched, distribution of immediate stinging pain; hatched, deep aching pain; stippled, painless tingling

The production of referred hypoalgesia by procaine injections alone is inconstant, but, if saline solution is first injected and procaine is injected into the same site soon after the referred pain from the saline solution has come on, this pain is usually rapidly curtailed Equally, if pain is already present from a local lesion—e g, herpes zoster or a painful scar—procaine injected into the appropriate interspinous segment will often produce a sustained reduction in pain and hyperalgesia, this has useful clinical applications

Two points interested us in connection with these induced pains

(1) *How long after the saline solution has produced referred pain will a procaine injection into the same site abolish the referred effect?* The common referred effect—the deep aching pain—is usually waning spontaneously after ten to fifteen minutes, but in a milder form it may last much longer So far we have produced a pronounced and rapid change in the referred pain by injecting procaine up to five minutes after the injection of saline solution Our usual procedure is to leave the saline needle in situ and to inject procaine through this, but in so cases the analgesic effect has been produced by a separ injection into the same or a very nearby site

(2) *Will anæsthesia of the site of referred pain abolish pain?* Conflicting evidence has been produced on this po when the question of skin pain referred from a visceral sou has been investigated Several workers have reported relief pain by anæsthesia of the referred site (Weiss and Davis 19 Morley 1931), whereas others have been unable to achieve t (Woollard et al 1932, Livingston 1943) Possibly this appa contradiction is partly due to a lack of distinction betwe referred pain and the less common referred skin hyperalgesia tenderness Lewis (1942), for instance, suggested that t mechanism of these two might differ, the hyperalgesia depend on axon reflexes, and the pain on defective localisation A som what similar view was put forward by Wolff and Wolf (194 However, the suggestion of Doran and Ratcliffe (1954) that t cord centre for summation of impulses from two sources ha threshold above which reference occurs, may be a more sat factory explanation, because local skin anæsthesia may th only sometimes reduce summated impulses below thresho level The following case is relevant to this problem

Case 1—Here saline-induced unilateral referred ach pain and skin hyperalgesia both occurred in the C7 segme "freezing" the hyperalgesic skin with ethyl-chloride sp both abolished the hyperalgesia and greatly reduced t referred aching As the effect wore off, apart from the transi perversion of sensation that always follows local ethyl-chlor anæsthesia, the hyperalgesia did not return and the dull ac also remained less These later effects may simply have be the natural waning of the referred sensations, but the imm diate effect was striking and occurred when the sensations we obtrusive and at their height

The mechanism of anæsthesia by freezing must differ fro that of nerve block, but in this setting it has the advantage th muscle and other deep afferents cannot be involved as th may with infiltration anæsthesia We can therefore argue th whatever effects are seen are those of alteration of skin sensati alone, whether by simple blocking of stimuli or possibly al by "bombardment" from an intense cold stimulus

The two following cases illustrate the ways in which t effects of injecting hypertonic saline solution may altered by spinal-cord lesions When spinothalam

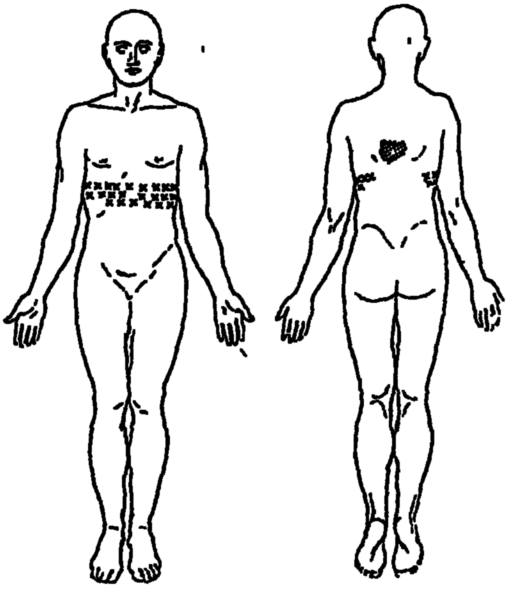

Fig 4—Effect of 0·3 ml of 6% saline solution injected between and D7 spinous processes in case 2 cross-hatched, distribution immediate stinging pain; small crosses, deep aching pain

(3) Any view of the neural mechanism involved in referred pain will have to try and explain all the facts At present there is a dichtomy of views into those concerned with peripheral mechanisms (such as pattern of peripheral sensory innervation, axon branching, and antidromic impulses) and those postulating a more central mechanism (such as a common sensory neurone pool in a segment of interconnected segments of the cord) This dichotomy seems unnecessary There is no reason why each mechanism should not be involved in some of the effects noted, nor indeed why both should not be involved together

Summary

The induction of referred pain by hypertonic saline solution injected into the interspinous ligaments and of referred hypoalgesia by similar injection of procaine in a healthy person is described

The modification of such referred phenomena in cases of spinal-cord lesions is described and discussed

A case of post-herpetic pain with referred phenomena and their modification by interspinous saline and procaine injections is described and discussed

This paper was read by one of us (C W M W) to the section of neurology of the Royal Society of Medicine, and we have to thank the honorary editors of the society's *Proceedings* for permission to publish

LEUKÆMIA. DOUBTS AND DIFFICULTIES

A J Lea
M B Birm
SENIOR MEDICAL OFFICER, MINISTRY OF PENSIONS AND NATIONAL INSURANCE, NORCROSS, BLACKPOOL

John D Abbatt
M B Edin , D M.R.
MEDICAL RADIOBIOLOGIST, GENERAL ELECTRIC COMPANY LTD , ATOMIC ENERGY DIVISION, ERITH, KENT

While engaged in a survey of the data on leukæmia contained in the records of the Ministry of Pensions and National Insurance (Abbatt and Lea 1957, Lea and Abbatt 1957) we have been much impressed by certain fundamental uncertainties the true incidence of leukæmia in the general population, the apparent increase in the death-rate from leukæmia in the general population in 1911–55, and the identification of the various types of leukæmia We attempt here to estimate the extent of these doubts

True Incidence of Leukæmia in General Population

In any disease which is not compulsorily notifiable the only evidence on which an estimate of its incidence can be based is provided by the certified death-rate In many diseases the death-rate can give no information about the incidence, but leukæmia is so extremely fatal that the death-rate must approximate very closely to the incidence If, therefore, it could be assumed that all cases of leukæmia were diagnosed, very probably no serious error would be introduced by taking the death-rate as the incidence

Unfortunately there is no guarantee that all cases of leukæmia are diagnosed, nor do we know of any method of estimating the size of the discrepancy There seems to be little doubt that an unknown proportion of cases diagnosed either as aplastic anæmia or as agranulocytosis are cases of leukæmia in an aleukæmic phase We have found 119 cases so diagnosed in the records of the Ministry of Pensions and National Insurance, which contain copies of the full notes, both Service and civilian, and in 18 of these (15%) we think the diagnosis is doubtful Our reasons for these doubts range from pathological reports—e g , " The predominating cell is not a typical lymphocyte but rather bigger with scanty cytoplasm, it lies somewhere between a lymphocyte and a lymphoblast, a few are definitely lymphoblasts "—to frank statements—e g , " The possibility that the aplastic anæmia may have been preceded by an aleukæmic type of myeloid leukæmia cannot be completely ruled out " At this date it is too late to do anything more than express doubts about these cases Even if pathological specimens were obtainable, it seems very unlikely that any firmly based conclusions could be reached

An unknown proportion, almost certainly small but sufficiently large to affect the apparent incidence of leukæmia, of adults over middle age certified as dying from cerebral hæmorrhage have no doubt died in that way, but the cause of the hæmorrhage has been leukæmia and not cardiovascular disease Similarly, some cases of acute leukæmia in infancy may be confused, in the absence of hæmatological investigation, with various acute infections

On the other hand, it seems very improbable that a death will be certified as due to leukæmia unless hæmatological investigation has been made No such case was found in our 691 cases from the records of the Ministry of Pensions and National Insurance It therefore does seem legitimate to conclude that the death-rates from leukæmia given by the Registrar General (1912–56) for 1911–55, do not err in the direction of overestimation, and that the rates given can be regarded as minimal

However, it does not follow that this will continue to be so The publicity recently given to the effects of radiation and the occurrence of leukæmia in irradiated cases of ankylosing spondylitis, goitre, persistent thymus, &c , must have produced some degree of " leukæmia-mindedness " in the medical profession In what direction, and to what extent, such a state will affect the certification of death from leukæmia it is impossible to say, but some effect seems to be inevitable Because of this we are of the opinion that the certified death-rates from leukæmia for the next few years are likely to be unreliable

Apparent Increase in Death-rate from Leukæmia in 1911–55

Since 1911 there has been a great increase in the apparent death-rate from leukæmia For males of all ages, the death-rate per thousand living in England and Wales in 1911–15 was 0 012 and for 1951–55 0 053 The corresponding figures for females were 0 010 and 0 043 (R A M Case and J T Pearson, unpublished) The male rate has increased 4 4 times and the female 4 3 This suggests that the factors responsible for the increase apply equally to both sexes These apparent increases, however, have not been uniformly distributed over the various age-groups, the greatest changes being in infancy and had had severe pain, felt in the skin in the affected dermatomes and deeply beneath it, almost entirely anteriorly The area rapidly developed a typical protection hyperalgesia, and when seen she could not endure even the lightest touch to the affected area without experiencing severe, diffuse, and intensely unpleasant pain Apart from this she had a mild hypertension She did not complain spontaneously of any symptoms referable to her cardiovascular system, but on direct questioning she described effort angina It appeared as a slight feeling of substernal constriction and an aching pain referred down the left arm rather diffusely, but more ulnar than radial It could be induced fairly consistently by walking briskly twice round the ward It subsided within a few minutes of resting Fig 6 shows the distribution of pain and the site of her zoster scarring

Intercostal block —The patient was given an intercostal block of 2% lignocaine to the D3 and D4 spaces About 10 ml was infiltrated in the posterior axillary line The post-herpetic pain was immediately reduced The hyperalgesia was abolished and the skin could be handled without discomfort The effect lasted about an hour and a half During this time the patient discovered that she could walk round the ward without inducing her usual anginal pain This was put to the test and although she had the usual slight breathlessness she was emphatic that she had no arm pain

Interspinous injection —In the routine treatment of her post-herpetic neuralgia she was given procaine into the D3 and D4 interspinous ligaments This relieved both the herpetic pain and the angina, the effect lasting about two hours On another occasion hypertonic saline solution was injected into the D3 and D4 interspinous sites This produced some increase in the herpetic pain and considerable aggravation of the hyperalgesia at the edges of the scarred area The anginal pain was not induced, however, and her usual exertion, undertaken when the herpetic pain was aggravated, did not produce any arm pain After repeated saline plus procaine injections to the D3 and D4 interspinous areas over a period of some days post-herpetic pain and hyperalgesia were permanently reduced Local massage and vibration to the scarred area were made possible, and with this she has remained comfortable for a six-month follow-up period

Discussion

The response of saline-induced pain to procaine injected at the saline site shows that referred pain, after its inception, may still depend on impulses from its primary activating focus If chemical change at the site of reference is responsible for it, such change must be very labile and maintained in some way by the primary focus

Anæsthetising the skin over the region to which pain is referred also appears to modify the referred pain, as shown in case 1 This is not incompatible with the previous observation if one assumes that part of the mechanism of reference is a summation of sensory inflow in the cord In that case reducing *any* impulses which pass to the centre of summation may reduce the referred sensation

A similar problem is posed by the observations in case 4 Weiss and Davis (1928) reported temporary abolition of angina by anæsthetising the area of skin reference In case 4, however, even if we assume a post-fixed brachial plexus, anæsthesia of an area of painful skin a segment or two away abolished the anginal pain Even when the painful skin area was rendered hypoalgesic as a referred phenomenon from anæsthesia of deep midline structures in the same segment, this also reduced the anginal pain It is difficult to imagine anything more peripheral than a cord mechanism being responsible for this The fact that temporary exacerbation of the herpetic pain by saline injection seemed to reduce anginal pain is also compatible with a cord mechanism in which stimuli may compete for a common afferent pathway, but competition for cerebral representation (Lewis 1942, Doran and Ratcliffe 19 would also explain it

The abolition of referred skin hyperalgesia, as dis from pain, by anæsthetising the site of reference, wh is also illustrated in case 1, is to be expected because t hyperalgesia is elicited by stimulation of the affected sk

Mackenzie (1909) emphasised that it was almost alw pain that was referred, rather than any other sensati This has at times been used as an argument that refere is largely psychological In case 2 there was clear reference of sensation to both sides of the body in the segment, but on the side served by the damaged spin thalamic tract the sensation was not painful This sugges that conduction and redistribution of impulses occur i the cord, whatever more peripheral mechanism is involv In case 2 also referred sensation which *was* painful w felt on both sides of the body at the D6 level, but it differ in quality from the pain felt in the upper limb As a res of the cord lesion in case 2 the appreciation of pain an temperature in the skin and pain from the compress of skeletal muscle were absent on clinical testing of t right side It therefore seems that the pathways in th cord for these sensations may differ from those subser the unpleasant sensation that this patient experien bilaterally

Kellgren (1939) and others have described a delaye onset to referred pain and hyperalgesia and have pointe out that reference is sometimes only approximatel segmental The hyperalgesic episode in case 3 was qual tatively similar to those occasionally observed at the site referred pain and aching following the midline injectio of saline solution in healthy people However, in case it was referred some six segments away from that of th saline injection, moreover it appeared at the upper lev of the clinical sensory deficit It is difficult to escape th conclusion that this delayed referred sensation involve a spinal-cord mechanism in its mode of reference and wa in some way bound up with the cord lesion suggested b the clinical findings Nathan (1956) describes a simil reference of pain beyond segmental limits in cases bot with and without lesions of the spinothalamic tract H also considers that this reference takes place at spinal-cor level, and he discusses in detail the possible anatomic and physiological basis for it The time sequence in case is also of special interest because a mechanism apparentl activated by the saline solution took up to three quarter of an hour to manifest its clinical effects

In conclusion we emphasise three points

(1) The clinical implications of these induced referred pai and other effects have still not been fully explored The application may be therapeutically rewarding, but (perhap more important) the methods can readily be applied to health people to give a wider and potentially more valuable field study

(2) It must be accepted that the response to hyperton saline solution varies Occasionally there may be no referr effect at all The same effect cannot always be reproduced the same person even with seemingly identical technique Th structure of the nervous system, the activity of the sens neurone pool, learnt and innate reactions to pain, and, partic larly, the patient's powers of observation may all introdu variations and apparent discrepancies The facts are large what the patient says he feels, and accurate description is n always easy for him The need for such accuracy is illustrate in the confusion between referred pain and referred hype algesia which has certainly arisen at times Nevertheless furth observations in this field are clearly worth while and will n doubt establish an agreed body of facts

type was changed during the course of the illness in 102 (16 2%) Of these 102 cases 72 were acute (as defined above) and 30 chronic. Of the 630 cases 370 were acute and 260 chronic, hence the changed diagnoses occurred in 19 5% of acute cases and 11 5% of chronic It is generally agreed that great difficulties exist in determining the cell type in many acute leukaemias, hence we were not surprised to find differences of opinion in such cases We were particularly surprised to find differences of opinion in so many chronic cases

The details of the changes in diagnosis of the cell type were as follows

Diagnosis on Peripheral Blood		*Diagnosis on Peripheral Blood*	*No of cases*
Myeloid	to	Lymphatic	4
Myeloid	to	Monocytic	2
Lymphatic	to	Myeloid	12
Lymphatic	to	Monocytic	4
Monocytic	to	Myeloid	4
Monocytic	to	Lymphatic	2
Diagnosis on Peripheral Blood		*Diagnosis on Sternal Marrow*	
Myeloid	to	Lymphatic	2
Myeloid	to	Monocytic	2
Lymphatic	to	Myeloid	13
Lymphatic	to	Monocytic	3
Monocytic	to	Myeloid	3
Diagnosis on Sternal Marrow		*Diagnosis on Sternal Marrow*	
Myeloid	to	Lymphatic	1
Myeloid	to	Monocytic	2
Lymphatic	to	Myeloid	1
Diagnosis on Sternal Marrow		*Diagnosis on Peripheral Blood*	
Myeloid	to	Lymphatic	1
Diagnosis on Blood and/or Marrow		*Necropsy Diagnosis*	
Myeloid	to	Lymphatic	2
Myeloid	to	Monocytic	1
Lymphatic	to	Myeloid	9
Lymphatic	to	Monocytic	3
Monocytic	to	Myeloid	3
Monocytic	to	Lymphatic	1

In 1 case lymphatic leukaemia was diagnosed on lymph-node biopsy and changed to myeloid at necropsy, but certified as lymphatic. 1 case was only diagnosed at necropsy as leukaemia of uncertain type and certified as lymphatic leukaemia 1 case was diagnosed on peripheral blood as ? lymphatic, ? monocytic leukaemia, and as myeloid at necropsy In 16 cases three diagnoses were made 9 of these reverted to the original diagnosis, but in the 7 others all three possible diagnoses were made.

Six changes of diagnosis are possible, and all of them were made myeloid to lymphatic 10, myeloid to monocytic 7, lymphatic to myeloid 35, lymphatic to monocytic 10, monocytic to myeloid 10, and monocytic to lymphatic 6

Equally remarkable was the finding that in 30 cases the diagnosis on the death certificate differed from the necropsy or haematological diagnosis. This is a singular finding

The evidence provides no grounds for regarding the second or third diagnoses as preferable to the first. In most of these cases no doubts were expressed about the original diagnosis Most of the changes were made when the patient was moved from one hospital to another and reinvestigated. These findings necessarily throw much doubt on the value of the diagnoses in those cases in which the patient was not transferred. The question must arise would there have been a change in the diagnosis of cell type if the patient had been investigated in another hospital? It cannot be emphasised too strongly that, although these cases of leukaemia occurred in members of the Forces, the great majority of the investigations were made in the civilian hospitals of this country It should also be realised that most of the diagnoses were made by general pathologists and not by haematologists, and that though these findings are generally applicable to the United Kingdom they may differ from the results of the highly selected sample that would be obtained from teaching hospitals

It is clear that we cannot accept our findings on the change in cell type during the past fifteen years as having any real meaning A change may be taking place, but the possibility of wrong diagnosis is far too great for this to be anything more than a suggestion It is also evident that any attempt to draw conclusions from the cell type given on death certificates is quite unjustifiable at present.

The remedy for this unfortunate position is not for us to discuss, but it is evident that the confusion on the type of leukaemia is very widespread A case of particular interest in this respect was one in which, after full haematological investigation, the patient was, with complete notes, transferred to another hospital and at once reinvestigated on the grounds that the clinical picture did not fit the haematological one. In view of the uncertainty about cell type which we have shown to exist such a statement seems to have little justification but it certainly indicates a very confused state of affairs

Summary

The deaths from leukaemia given in the Registrar General's Statistical Reviews are unlikely to be over-estimates

Although some of the apparent increase in the death-rate from leukaemia in 1911–55 is due to improvement in diagnostic facilities, the greater part of it appears to be real

The diagnosis of cell type in leukaemia is, at present, too unreliable for conclusions to be drawn from it, this particularly applies to conclusions drawn from death certificates

We are indebted to Prof J V Dacie and Prof L. J Witts for helpful advice and criticism in the preparation of this paper, and to the Chief Medical Officer of the Ministry of Pensions and National Insurance for permission to publish data taken from the records of the Ministry

CITY GENERAL HOSPITAL, SHEFFIELD

IN Sheffield the epidemic of influenza, due to the Asian variety of influenza-A virus, was at its height in September and October, 1957 In these two months 140 patients with pneumonia were admitted to the general medical wards of this hospital

We review these cases here and discuss some factors that affected prognosis The association between influenza-A virus and *Staphylococcus aureus* (coagulase-positive) is well recognised, and we emphasise the

TABLE I—RESULTS OF BACTERIOLOGICAL EXAMINATION OF SPUTUM AND NECROPSY MATERIAL IN 140 CASES

Organism	No of cases
Staph aureus	38 (*27%*)
Pneumococci	12 (*9%*)
H influenzæ	5 (*4%*)
Friedländer's bacillus	7 (*5%*)
β-Hæmolytic streptococci	2 (*1%*)
Coliform bacilli	10 (*7%*)
No significant organisms	65 (*46%*)
No bacteriological examination	1 (*1%*)
Total	140

importance of this organism both as an early and as a late bacterial invader

Methods

A retrospective study was made of the case-notes and laboratory records for the months of September and October The criterion for inclusion in the series was evidence of consolidation of the lung demonstrated by either radiography or necropsy

In the laboratory each sputum was cultured aerobically on a horse-blood agar plate Necropsy material was cultured on a blood-agar plate both aerobically and anaerobically and on a MacConkey agar plate The plates were read after overnight incubation at 37°C In the interpretation of cultures the presence of bacterial pathogens, especially *Staph aureus*, was reported only when they were considered to be present in significant numbers It has been found in this laboratory that the use of a heated blood ("chocolate") agar plate did not appreciably increase the isolation-rate of *Hæmophilus influenzæ*, so long as small colonies, especially those showing satellitism in the presence of staphylococci, were fully examined Most of the necropsy specimens, however, were cultured on chocolate-agar as well as on blood-agar

Staph aureus was identified by the slide and/or the tube coagulase test, pneumococci by their sensitivity to ethylhydrocupreine ('Optochin') *H influenzæ* by satellitism around a colony of *Staph aureus* on a blood-agar plate, and coliform bacilli by colonial morphology All organisms were checked for their morphological appearance When pathogenic bacteria were not isolated, the result was recorded as "no significant organisms"

Sensitivity was tested by placing antibiotic discs on a blood-agar plate inoculated with the organism on the surface, and the results were read after overnight incubation at 37°C The organisms were tested against aureomycin, penicillin, streptomycin, chloramphenicol, erythromycin, and sulphonamides, and were recorded as being either sensitive or resistant

Results

The results of the culture of sputum and necropsy material are set out in table I, which shows that *Staph aureus* was isolated from 27% of the cases and pneumococci and *H influenzæ* from only 9% and 4% respectively

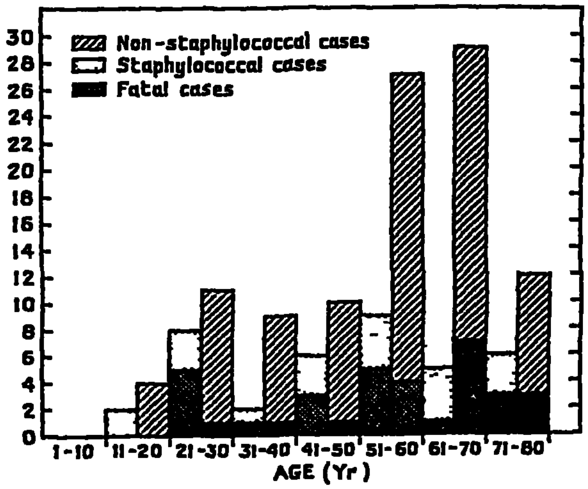

Fig 1—Age-distribution and mortality in staphylococcal and non-staphylococcal pneumonia

The cases can be divided into two large groups those in which *Staph aureus* was isolated, and those in which it was not

The incidence and mortality, by age, in the staphylococcal and in the non-staphylococcal groups are given in fig 1 In the staphylococcal group there were 38 cases with 18 deaths, a mortality of 47%, and in the non-staphylococcal group there were 102 cases with 16 deaths, a mortality of 16% The overall mortality of the series was 24% There was no clear sex difference in either group

A further comparison of incidence and mortality, in relation to pre-existing disease, is set out in table II Two large groups may be noted—one with no pre-existing disease and the other with chronic chest disease There are four other small groups which are too small for comparison In the two larger groups the mortality was much greater when *Staph aureus* was present

TABLE II—COMPARISON OF INCIDENCE AND MORTALITY IN STAPHYLOCOCCAL AND NON-STAPHYLOCOCCAL CASES ON THE BASIS OF PRE-EXISTING DISEASE

Clinical state	Non-staphylococcal group		Staphylococcal group	
	Total no	No of fatal cases	Total no	No of fatal cases
No previous disease	35	2 (*6%*)	19	8 (*42%*)
Chronic chest disease	48	8 (*17%*)	13	7 (*54%*)
Hypertension and ischæmic heart-disease	5	3	1	1
Pregnancy	4	0	2	1
Pregnancy and mitral-valve disease	3	1	1	1
Rheumatic heart-disease	7	2	2	0
Total	102	16 (*16%*)	38	18 (*47%*)

An analysis of the sex distribution according to age shows that males predominated in the older age-groups, because of the high incidence of chronic chest disease in this area The relatively larger number of females in the younger age-groups may be due to the more serious prognosis of postinfluenzal pneumonia in pregnancy and rheumatic heart-disease

There were 33 cases of pneumonia in women of child-bearing age (16–40), 10 of these were pregnant, 8 being in the third trimester (table II)

13 patients had valvular heart-disease, 11 of them having lesions of the mitral valve Of these 11 patients with mitral disease 9 were females, and 3 died (all females)

The antibiotic sensitivity of the strains of *Staph aureus* isolated from the 18 fatal cases are presented in table III Antibiotic-sensitive strains are those sensitive to aureomycin, chloramphenicol, penicillin, streptomycin, erythromycin, and sulphonamides Antibiotic-resistant strains are those resistant to aureomycin, penicillin,

TABLE III—ANALYSIS OF ANTIBIOTIC SENSITIVITY OF STRAINS OF *Staph aureus* ISOLATED FROM 18 FATAL CASES

No of days in hospital	Antibiotic sensitive strains	Antibiotic resistant strains
<1	9	0
2–7	3	2
8–14	0	2
15–21	0	1
22–28	0	1
Total	12	6

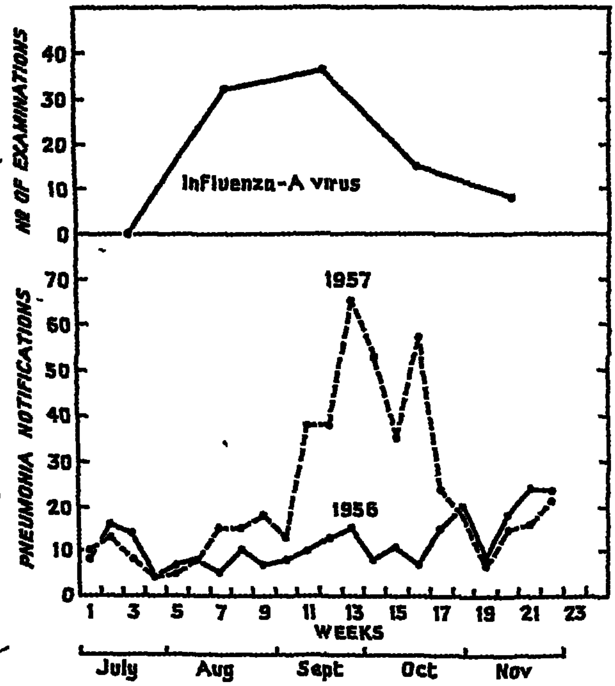

Fig 2—Pneumonia notifications to M O H, Sheffield, in 1956 and 1957 and numbers of cases in which influenza-A virus was found.

streptomycin, and sulphonamides and sensitive to erythromycin and/or chloramphenicol Erythromycin was the only one of the six antibiotics used in the laboratory routine to which all the strains of *Staph aureus* were sensitive

The culture results and the sensitivity of strains of *Staph aureus* isolated on admission to hospital and in hospital are shown in table IV

Discussion

The number of cases of infection with influenza-A virus diagnosed in the Public Health Laboratory, Sheffield, from all sources, is set out in fig 2, which also gives the number of pneumonia notifications to the medical officer of health, Sheffield, in September and October in 1956 and 1957 Fig 3 gives the admission-rate, by weeks of the 140 cases under discussion.

The results of the virus study reflect, to some extent, the prevalence in the community of infection by influenza-A virus These results, in conjunction with the increase in pneumonia notifications in September and October, 1957, compared with the previous year, and in conjunction with the admission-rate of the 140 cases to hospital, tend to support the view that most of the cases under review were, in fact, of postinfluenzal pneumonia Serological evidence of infection with, and isolation of, influenza virus A was made in a proportion of the cases Many of the patients gave a history of a typical influenzal illness preceding the pneumonia

The viruses of influenza B, C, and D (Sendai virus) were not detected in the community in comparable periods in 1956 or 1957 Influenza virus A was not detected in the autumn of 1956

The fact that most of the patients had been given antibiotics before admission to hospital may explain the large number of cases (46%) in which cultures of sputum and necropsy material did not reveal any pathogenic bacteria (table I) This supposition is supported by the 10 cases (7%) in which coliform bacilli were isolated from sputum, because these bacilli are often isolated from sputum cultures made during or immediately after antibiotic therapy

TABLE IV—ANTIBIOTIC SENSITIVITY AND RESISTANCE OF STRAINS OF *Staph aureus* ISOLATED ON AND AFTER ADMISSION TO HOSPITAL

No of patients with	No of survivors	No of fatal cases
Antibiotic-sensitive strains isolated on admission and thereafter	7	12
Antibiotic-sensitive strains isolated on admission, with antibiotic-resistant strains isolated later	2	0
No significant organisms isolated on admission, with antibiotic-sensitive strains isolated later	0	0
No significant organisms isolated on admission, with antibiotic-resistant strains isolated later	8	3
Antibiotic-resistant strains isolated at first bacteriological examination	3	3
Total	20	18

Thus the bacteriological results in this series are not directly comparable with any of the series in the pre-antibiotic era, because many of the pathogenic organisms —e g, pneumococci and *H influenzæ*—may have been killed or had their growth suppressed If we accept that the low isolation-rates for pneumococci and *H influenzæ* (9% and 4% respectively) were due to the use of antibiotics before admission to hospital, the isolation-rate of *Staph aureus* (27%) may be lower than the true incidence Stuart-Harris (1953) found that *Staph aureus* was isolated from 20% of cases during an influenzal period and from 4% of cases during a non-influenzal period

In the Public Health Laboratory, Sheffield, during 1955–57 the percentage number of sputa from which *Staph aureus* was isolated increased during influenzal epidemics (L Robertson and J E M Whitehead, to be published)

The greater severity and mortality of the cases infected with *Staph aureus*, along with the prevalence of the organism in sputa during influenzal periods, suggest an association between the organism and the virus Whether this is an additive or a synergistic effect is open to speculation

Of the cases infected with *Staph aureus* there are two groups large enough for comparison (table II) In the "healthy group" there were 19 patients of whom 8 (42%) died, whereas in the "chronic chest group" there were 13, of whom 7 (54%) died As would be expected, the average age of the "chronic chest group" was higher than that of the "healthy group" owing to increasing prevalence of chronic bronchitis in the older age-groups In 13 of 61 cases (21%) in the "chronic chest group", and in 19 of 54 cases (35%) in the "healthy group" *Staph aureus* was isolated from either sputum or necropsy material

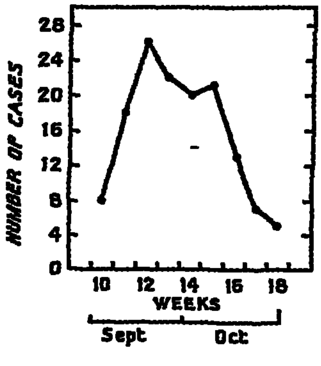

Fig 3—Distribution of admissions of 140 patients with pneumonia to hospital

Of necessity the patients admitted to hospital were selected Those who had previously been healthy were admitted because they had a serious illness Several had the syndrome of " peculiar cyanosis " and " gelatinous exudate " described by French (1920) Necropsy in these cases showed necrosis, in whole or in part, of the tracheobronchial epithelium The trachea and bronchi were bathed in bloodstained purulent material Microscopy showed numerous gram-positive cocci, and pure growths of *Staph aureus* were obtained on culture There was considerable pulmonary œdema, a thin serous bloodstained fluid exuding from the lungs on pressure 1 patient presented the appearance of toxic myocarditis In the " chronic chest group " the infection often precipitated respiratory or cardiac failure, and in the fatal cases in this group necropsy revealed more often changes of a conventional pneumonic pattern However, some tracheal and bronchial subepithelial hæmorrhage was present in most cases

The hospital environment is contaminated with *Staph aureus* With the increasing use of antibiotic and chemotherapeutic agents strains resistant to several such agents can be isolated from the noses of members of the hospital population, blankets, superficial skin lesions, &c In a disease such as influenza, where a possible association between the virus and *Staph aureus* can be shown, there may be a danger in introducing a patient with a postinfluenzal pneumonia not due to *Staph aureus* into such an environment It is thought that hospital infection did take place in this series Thus, an analysis of the antibiotic sensitivity pattern of the strains isolated from all the cases of staphylococcal infection shows that 21 cases (table IV) had sensitive strains on admission to hospital, and that 2 of these later acquired a resistant strain There were 11 patients from whom *Staph aureus* was not isolated on admission to hospital but who subsequently showed evidence of infection with resistant strains Most of the resistant strains were isolated after the first week in hospital, three of these were isolated after the temperature had subsided and the patients were recovering from the infection No cases became superinfected with sensitive strains in hospital

Table III, where the antibiotic sensitivity of the strains of *Staph aureus* isolated from the 18 fatal cases is presented, shows that, in cases which were fatal within twenty-four hours of admission to hospital, all the strains isolated were sensitive to aureomycin, chloramphenicol, penicillin, streptomycin, erythromycin, and sulphonamides—i e, the patients were infected with strains having the antibiotic sensitivity pattern that one would expect to find outside the hospital community From the second to the seventh day after admission to hospital there were 5 deaths From 3 of these 5 patients antibiotic-sensitive strains were isolated, from the 2 others antibiotic-resistant strains were isolated post mortem, no previous bacteriological examination having been made In all, there were 6 fatal cases infected with resistant strains, and in 3 of the 6 cases resistant strains were isolated from the first specimens examined Possibly the 3 patients were infected with antibiotic-resistant strains before entering hospital, but such strains are not commonly found outside the hospital community These infections may well have been acquired while these patients were in hospital

An example of infection in hospital with antibiotic-resistant strains of *Staph aureus* was seen in one of the wards where 7 patients with pneumonia were admitted From 3 patients *Staph aureus* phage-type 77 was isolated, and these three strains, which were not present in the first specimen of sputum examined, were sensitive to erythromycin and chloramphenicol only From the 4 other patients antibiotic-sensitive strains were isolated, one strain was type 53, one type 52A, and the two others were not typed

Bacteriophage typing of *Staph aureus* was done on strains isolated from 16 cases There was no predominant type

The treatment of the fulminating staphylococcal infections is very difficult, because it is necessary to treat both the bacterial infection and the attendant pulmonary œdema and peripheral circulatory failure 14 such patients died within the first week of admission to hospital, and all had been treated in hospital with massive doses of antibiotics, including erythromycin and chloramphenicol Despite this treatment antibiotic-sensitive strains of *Staph aureus* were isolated from 12 of the patients post mortem In contrast the less severely affected patients responded well to antibiotics, and those infected in hospital with antibiotic-resistant strains responded well to the antibiotics indicated by the in-vitro sensitivity tests

In hospitals where patients are being treated with antibiotics the nasal flora is suppressed, and it is possible that the nares can then become colonised by the antibiotic-resistant strains of *Staph aureus* present in the hospital environment Gould and Cruikshank (1957) have successfully suppressed *Staph aureus* in the nares with antibacterial creams Possibly hibitane, combined with either neomycin or bacitracin, as a nasal cream, as they suggest, would be of prophylactic value in patients admitted to hospital with postinfluenzal pneumonia who are not infected with *Staph aureus* on admission but who are liable to become superinfected with antibiotic-resistant hospital strains of *Staph aureus*

It would be interesting to know whether the patients in whom postinfluenzal staphylococcal pneumonia developed were, in normal circumstances, nasal carriers of the organism, and whether the lung infection was derived from the strains present in the nose If this were so, the 30–40% of the community at large who are nasal carriers of *Staph aureus* would be at a special risk during influenzal epidemics

Summary

During the influenza epidemic in the autumn of 1957 140 patients with pneumonia were admitted to this hospital

Among the 38 patients infected with *Staph aureus* the mortality was noticeably greater (47%) than in the remainder (16%)

There was evidence that 13 of the 140 patients were infected in hospital with strains of *Staph aureus* which were resistant to penicillin, aureomycin, streptomycin, and sulphonamides

We wish to thank the physicians of the City General Hospital under whose care the patients were admitted, Dr A J N Warrack for the necropsy findings, Dr J E M Whitehead for the virological investigations, Dr E H Gillespie for the results of staphylococcal phage-typing, and Dr E H Gillespie and Dr J Beasley for advice and criticism

METASTATIC PANOPHTHALMITIS FOLLOWING COMMONPLACE SURGICAL INFECTIONS

MALCOLM H. GOUGH
M.B. Lond., F.R.C.S.
RESIDENT SURGICAL OFFICER, WEST KENT GENERAL HOSPITAL,
MAIDSTONE, KENT

PANOPHTHALMITIS is an acute purulent infection involving all the coats of the eye and usually follows a perforating wound, whether this be operative or accidental. A further means of infection is by metastatic spread from some other focus, in these cases the panophthalmitis may present either as part of a general septicæmia or as an isolated lesion, and the true nature of an inflamed and painful eye may often remain obscure until irreversible damage has been done to delicate intraocular structures. If, however, panophthalmitis is recognised early, the sight of the affected eye may be saved.

Two cases are reported here not only because of the difficulty in diagnosis but also because of the rarity of panophthalmitis now that antibiotics are used more widely in early cases of general and ocular infection.

Case-reports

CASE 1.—A housewife, aged 28, reported to hospital on Feb. 17, 1957, with two weeks' history of a tender swelling of her left breast. She had previously always been well. Twenty-five days earlier she had given birth to twins and had been given stilbœstrol tablets immediately afterwards to suppress lactation. On the tenth day post partum she had in her left breast a painful swelling which was diagnosed by her doctor as an incipient breast abscess and treated with penicillin injections for a week. This produced marked symptomatic improvement, and she then applied kaolin poultices for a further week, during which time her symptoms recurred.

On examination she looked ill and had an obvious large breast abscess beginning to point vertically above the nipple. No other abnormality was found. Under general anæsthesia the abscess was incised, and about 8 oz. of thick yellow pus was evacuated from a multilocular cavity occupying the greater part of the breast. The loculi were broken down, and the cavity was drained.

Postoperative course.—On the fourth postoperative day the patient complained of watering and irritation of her right eye. Examination showed mild conjunctival injection but little else. She was treated with sulphacetamide-sodium ('Albucid') eyedrops for presumed conjunctivitis. Next day the irritation had changed to pain, her vision had become blurred, and she had ciliary injection and chemosis. Acute iritis was diagnosed and treatment begun with atropine eyedrops and hot bathing. On the sixth day hydrocortisone eyedrops were prescribed in addition to the atropine. The pain and chemosis, however, gradually increased, and on the seventh day a rise in tension of the globe was noticed. This, with the increased pain, was thought to be due to secondary glaucoma, and acetazolamide ('Diamox') tablets 500 mg. initially, followed by 250 mg. four times daily, were given. By the ninth day the pain had become very severe and throbbing and radiated to the frontal region, teeth, and nose. Chemosis was gross, as was œdema of the lids, and vision was restricted to appreciation of bright light. At this stage panophthalmitis was suspected, and a retrobulbar injection of crystalline penicillin 1,000,000 units with 2% lignocaine 0·5 ml. and hyaluronidase 1 ml. was given. Hot bathing was continued, streptomycin 0·5 g. was injected intramuscularly twice daily, and the patient was heavily sedated.

Operation.—The patient's condition having remained unchanged, on the twelfth day, under general anæsthesia, the sclera was incised at the level of the pars plana of the ciliary body. Thick pale-yellow pus was liberated. Exploration of the orbit revealed no further pus. The cornea was then incised, and pus was irrigated from the anterior chamber. Complete seclusio pupillæ was found.

Postoperative course.—Next day the patient's condition was greatly improved, the œdema, pain, and chemosis all gradually settled, and two weeks later she was discharged with a slightly painful and blind eye. During the following six months the eye became painless and then shrunken. Her breast healed normally, and at no time was there evidence of any other metastatic lesion. Her temperature was raised on admission but fell after the incision of the breast abscess. It did not rise above 99°F until the ninth postoperative day, when the panophthalmitis was fully established.

Laboratory investigations.—From both the breast and the eye similar organisms were cultured, namely coagulase-positive staphylococci sensitive to streptomycin, terramycin, and chloramphenicol but resistant to penicillin.

CASE 2.—A diabetic woman, aged 46, attended hospital on Sept. 11, 1956, with a paronychia of her left index finger. She had this incised as an outpatient under local anæsthesia, and a small amount of pus was released. She was not given any antibiotics. A few days later she felt unwell and became pyrexial. On the advice of her doctor she rested in bed, but the malaise continued and she developed polydypsia and polyuria and became nauseated. On Sept. 23, 1956, she had noticed bilateral deterioration of vision, accompanied by pain in her left eye which radiated to the frontal region.

On admission to hospital on Sept. 25, 1956, her temperature was 100°F and she had glycosuria and acetonuria. Her eyelids on both sides were œdematous, there was bilateral ciliary injection, and both pupils were unresponsive to light. A cloudiness was visible in both anterior chambers, and vision was restricted in the left eye to appreciation of light and dark only, and in the right eye to appreciation of coarse hand movements.

Diagnosis, treatment, and course.—Bilateral iritis with secondary glaucoma and uncontrolled diabetes was diagnosed, and treatment with cortisone and atropine eyedrops, and with insulin was instituted. On Sept. 28, 1956, her temperature had become normal although her eyes had improved only a little. On this day a trace of albumin and some pus cells were found in her urine, and on abdominal palpation a soft spleen tip was felt. Urine and blood cultures were made, and the true nature of the ocular condition was now recognised as probably a metastatic panophthalmitis secondary to septicæmia. Treatment with crystalline penicillin 8,000,000 units daily, streptomycin 2 g. daily, and chloramphenicol 2 g. daily was begun. By Oct. 2, 1956, although the right eye was slowly improving, the left eye had lost all vision and was painful and proptosed, and there was considerable periorbital œdema.

Operation.—On Oct. 3, 1956, under general anæsthesia, the left eye was explored, found to contain a large amount of pus, and eviscerated.

Postoperative progress.—This was satisfactory, the antibiotics being discontinued on Oct. 14, 1956. The gradual improvement of the right eye was maintained, which progress was hastened by two five-day courses of corticotrophin in the next six weeks, the first course being covered by a further week's course of chloramphenicol 2 g. daily and terramycin 2 g. daily. When the patient was discharged on Dec. 3, 1956, she had been stabilised (after some early difficulty) on insulin zinc suspension 56 units daily, her left eye had healed satisfactorily, and her right eye, in which the vitreous was still clearing, had a visual acuity of 1·5/60.

Follow-up.—A year later, in November, 1957, her visual acuity was 6/60, and some scarring was visible above the macula, this presumably being the site of the original choroidal or retinal abscess. Again in this patient, in spite of septicæmia, there was no high pyrexia. At no time did her temperature rise above 101°F which was recorded only on one occasion.

Laboratory investigations.—Unfortunately the pus from the infected finger was not cultured. The blood-sugar levels on Sept. 26, 1956, were 235 mg. per 100 ml. in the morning and 255 mg. per 100 ml. in the evening. On Sept. 28, 1956, cultures of blood and urine (catheter specimens) both grew *Staphylococcus aureus* slightly sensitive to penicillin and sensitive to chloramphenicol, streptomycin, and terramycin, and the number of white blood-cells was 8900 per c mm (polymorphs 84%, lymphocytes 14%, monocytes 2%) On Oct 2, 1956, three days after the start of antibiotic therapy, a blood-culture again yielded staphylococci On Oct 16, 1956, and thereafter blood-cultures proved negative

Discussion

Metastatic infection of the eye was first recognised by Virchow (1856) and Axenfeld (1894) published a series of such cases Most of the cases recorded since occurred in pre-antibiotic days, when loss of the affected eye was almost inevitable Donahue (1943), however, reported a recovery from panophthalmitis in a man, aged 52, who developed the infection a week after perurethral prostatectomy and was successfully treated with sulphadiazine Today, with prompt antibiotic treatment (promptness is the important factor), it may be possible to save the vision of the affected eye in a large proportion of cases

The primary lesions in published cases have ranged from otitis media and pneumonia to furunculosis (Spicer 1907), and the most usual infecting organisms have been streptococci, staphylococci, and (less commonly) coliform bacilli The presence of frank septicæmia (as in case 2) is by no means an invariable accompaniment of metastatic panophthalmitis, but septicæmia was probably the cause of death in many of the earlier published cases

Typically panophthalmitis is of dramatic onset, but it was not so in these two patients Again, the temperature is commonly considerably raised, but in these two cases pyrexia was not prominent in the clinical picture The usual presenting symptoms are pain in the eye, malaise, headache, and drowsiness, and the signs are those of conjunctival and ciliary injection, œdema of the lids, and chemosis and a hazy appearance of the cornea The iris appears "muddy", and the posterior corneal surface becomes covered with precipitates A vitreous haze develops, and eventually this haze increases until, on retinoscopy, all view is obscured and the yellow reflex is obtained These signs may develop in a few hours or take several days to become manifest Eventually the pain becomes very severe, the intraocular tension rises considerably, and the eye becomes fixed and proptosed The differential diagnosis is from an intraorbital, as opposed to an intraocular, abscess

The earlier that treatment is begun the better because, once suppuration has started, the delicate intraocular structures become irreversibly damaged (Duke-Elder 1940, 1954), and, even if the eye is saved, the end-result, so far as visual acuity is concerned, may be disappointing With the first symptom or sign, treatment with atropine eyedrops and local heat, which may be applied by bathing or by short-wave diathermy, should be instituted Cortisone locally and either corticotrophin or cortisone systemically should be tried The antibiotic to be given will depend on the sensitivity of the organism, which may be assumed if the organisms of the original lesion have been cultured as in case 1 If the organism is not known, a conjunctival swab should be taken and treatment started with local and systemic penicillin Locally penicillin may be administered by subconjunctival or retrobulbar injection It is probably wise, owing to the common occurrence of penicillin-resistant infections, to combine this with some other antibiotic therapy Penicillin given systemically does not pass the blood-aqueous barrier, hence the need for local and systemic administration, although sulphonamides do pass this barrier Of the other antibiotics the most satisfactory, after experimental and clinical trials, appears to be chloramphenicol in a dosage of up to 6 g daily (Leopold et al 1950) This may also, with advantage, be applied locally as drops or ointment Terramycin appears to be relatively unsatisfactory (Sorbsy et al 1953) If a combination of antibiotics are given at any one time, it should be remembered that they do not always exert a synergistic effect Streptomycin may also be given by subconjunctival injection, and the intraocular levels obtained are higher if adrenaline is added to the injection

Sorsby and Ungar (1958) have favourably reported on the use of neomycin in intraocular infections Neomycin is a true broad-spectrum antibiotic and thus is effective against the organisms likely to be the cause of panophthalmitis Although clinical experience of its use is limited, for subconjunctival injection neomycin 0 5 g dissolved in 0 75 ml of water to which 0 25 ml of 1 1,000 adrenaline has been added is recommended Neomycin is toxic, so probably not more than 2 g should be administered by this route Again, another antibiotic should be given systemically in metastatic panophthalmitis

If the condition is recognised only at a late stage or does not respond to vigorous antibiotic therapy, resort will have to be made to surgery Usually evisceration is the operation of choice because enucleation involves the danger of spread of the infection to the subarachnoid space round the optic nerve, leading to meningitis

It is interesting to note that the incidence of intraocular metastatic carcinoma is very low, even in patients with widespread carcinomatosis, about 70% of those which do occur are said to be secondary to breast carcinoma (Cohen 1937)

In both cases reported here acute iritis was diagnosed in the early stages In case 2 the true nature of the process was recognised with the development of signs of septicæmia, and prompt antibiotic treatment saved the second eye Although coincident but quite divorced ocular conditions are undoubtedly more common in such patients, any person presenting with an acutely inflamed eye and a recent history of pyogenic infection should be suspected of having metastatic panophthalmitis, especially if the tension of the globe is raised

Summary

Two cases of metastatic panophthalmitis, one following drainage of a breast abscess and one, which was bilateral, following a paronychia, are described

The infrequency of metastatic panophthalmitis and the importance of early antibiotic therapy, both local and systemic, if vision is to be saved, are noted

Any patient with an acute iritis and a recent history of pyogenic infection should be suspected of having metastatic panophthalmitis

I wish to thank Mr K W Wilkinson and Mr J S Phillpotts for help in preparing this paper and permission to publish case 1, and Dr J R Nassim for permission to publish case 2

Early in 1957 we began work on total cardiopulmonary bypass, hoping that within a year we could employ a heart-lung machine on patients requiring deliberate open cardiac surgery This limited aim has been achieved, and the techniques learnt in the laboratory have been translated to the operating-theatre Lillehei et al (1956) and Kirklin et al (1956) in the U S A had developed satisfactory bypass techniques well before we started, the most superficial study of their work reveals the stress they placed on painstaking laboratory preparation We outline here the work done by a team anxious to gain the knowledge necessary to carry out safe total cardiopulmonary bypass

The Apparatus

We use a Lillehei-deWall pump-oxygenator (deWall et al. 1957) (fig 1) The pump, a 'Sigmamotor T-6S',* has identical arterial and venous heads in which a length of latex tube is compressed against a spring-loaded back-plate by each of a series of twelve steel fingers in turn milking the blood along The speed of action, and thus the delivery-rate of each head is independently variable Blood passes from the caval cannulæ to the venous pump (In the last 11 perfusions we have used a gravity drainage venous well [deWall et al 1958]) From the pump the blood passes up a vertical tube, the oxygenator, into which oxygen is bubbled through a perforated disc at its lower end During this ascent the blood is oxygenated and then passes down into a wider tube, the debubbler, set at 25° to the horizontal and coated with a silicone antifoam (I C I M430 †) to break the bubbles, it flows from the debubbler into a long spiral tube, the helix, immersed in a thermostatically controlled water bath at a temperature of 41°C In the helix any remaining bubbles rise, so that blood leaving the base of the helix is bubble-free. The helix also acts as a reservoir in which the volume of blood can be accurately observed The arterial pump takes blood from the helix and passes it to the arterial cannula through a simple monofilament nylon-mesh filter, which also serves as an additional bubble trap

Apart from the latex in the pump heads all the tubing is of transparent polyvinyl chloride ‡ The various connections, including the perforated plate for introducing the oxygen, are made of highly polished stainless steel or nylon All apparatus in contact with blood is sterilised by autoclaving in sealed nylon tubular foil bags § Although providing a barrier to bacterial contamination, these bags are permeable to steam during autoclaving and allow subsequent drying

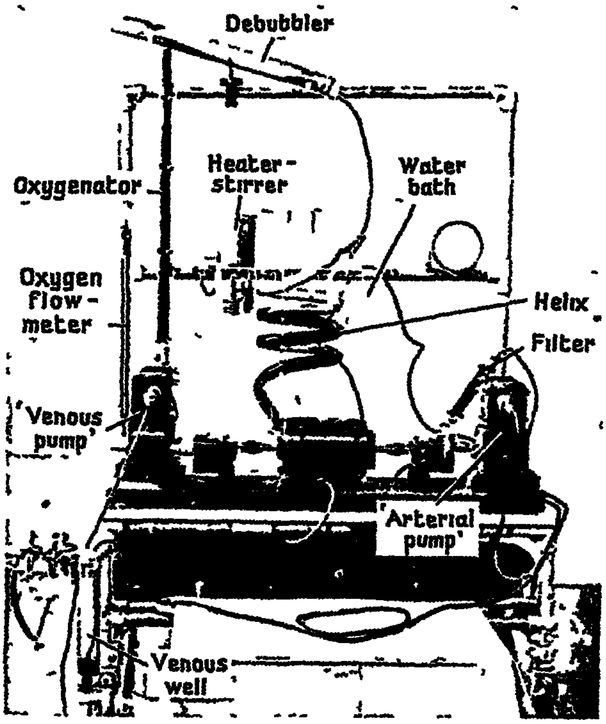

Fig 1—Lillehei-deWall heart-lung machine, with arterial and venous hoses connected.

Preliminary Studies

Before animal work was started, many hours were spent in handling the machine so that we became familiar with its behaviour It was found that, with correct adjustment of the back-plates, the pump output was independent of inflow pressures from −50 to +50 mm Hg and of outflow pressures up to 400 mm Hg

Oxygenation was studied using fresh heparinised venous ox-blood It was found that a ratio of oxygen to blood-flow of 5 1 by volume ensured 98% oxygenation at rates of flow between 500 and 800 ml per min of 24% oxygenated venous blood

Mechanical hæmolysis was also studied Plasma-hæmoglobin levels were less than 150 mg per 100 ml after continuous circulation of ox blood, equivalent to perfusion at 900 ml per min for one hour These experiments also showed that debubbling was satisfactory

Monitoring (fig 2)

A monitoring technique has been established to give continuous records of the aortic and inferior vena caval pressures, electrocardiogram (E C G), electroencephalogram (E E G), and œsophageal temperature (fig 2)

The recording apparatus is an Ediswan four-channel pen oscillograph The manometers used for measuring the pressures are of a valve transducer (R C A 5734) type modified from a design by Arnott et al (1951) Calibration is effected by connecting each manometer through three-way taps to a system filled with heparinised isotonic dextrose incorporating a pressure bottle and a valve ¶ as a precaution against air embolism This obviates the use of long fluid columns and thus gives a rapid and accurate method of repeated calibration.

The E C G electrodes are safety-pins inserted subcutaneously in each shoulder and the left leg The E E G electrodes are two tempered-steel pins varnished except for the tips lightly hammered into the frontal and occipital regions of the skull of the anæsthetised dog in the parasaggital plane An optional earth electrode is similarly sited in the midline over the frontal sinus A cut-out device connected with the diathermy foot pedal protects the E C G and E E G recorders when the diathermy is in use

No biochemical monitoring has been performed

Preliminary Animal Studies

None of the team had had previous experience of dog surgery or anæsthesia The monitoring apparatus was therefore set up on three dogs under anæsthesia and blood was collected for hæmolysis experiments In two of these dogs cadaver perfusions were performed in order to gain experience in making the necessary incisions and carrying out the cannulations No other acute experiments were done

Procedure

Every experiment was conducted under the same conditions as those in the operating-theatre The dogs used were unselected mongrels weighing 7 5–17 5 kg Large dogs were used as donors to provide blood to charge the machine No dog was obviously ill, and no preoperative treatment was given Preoperative hæmoglobin estimations and cross-matching of donor and recipient dogs were performed Agglutination was occasionally seen, incompatibility was then assumed, and the donor dog changed

Donor blood is collected by slow bleeding of the anæsthetised dog (vide infra) after cannulation of the carotid artery and external jugular vein Before bleeding, heparin 2 mg per kg of body-weight is given intravenously and the blood is collected into 500 ml bottles containing 9 mg heparin in isotonic dextrose solution The donor dog is killed Meanwhile the machine is assembled, using aseptic technique, and calibrated with physiological saline solution to give the desired flow-rate (this was originally 60 ml per kg body-weight per min , but recently has been increased to 80 ml per kg per min and above, giving total flows up to 1500 ml per min) The saline solution is then drained from the venous side of the machine and from the arterial side, leaving two inches in the helix and the arterial hose and filter full (280 ml) The machine is charged with 800–1000 ml of donor blood This provides a helix content during perfusion equivalent to approximately half a minute's flow (This is only half the amount in the helix recommended by Lillehei [deWall et al 1958] Though we were aware of this, we wished to economise on donor dogs Using the machine with this small charge provided a more stringent test of the efficiency of the helix and also gave less latitude for errors in handling the machine) The arterial and venous hoses are connected to each other, the pumps are started, and the blood is circulated The hoses are inspected until all bubbles have been removed from the arterial side

Anæsthesia

Anæsthesia is induced in the unpremedicated dog with thiopentone 10 mg per kg body-weight and succinylcholine chloride 1 mg per kg body-weight intravenously The dog is intubated and anæsthesia is maintained with nitrous oxide and oxygen in a semiclosed circuit incorporating a Waters' canister Increments of up to a quarter of the induction dose of barbiturate or relaxant are given as required Atropine 0 66 mg (gr $^1/_{100}$) is given intravenously at the time of induction and repeated later if excessive salivation occurs

The Surgical Approach

The dog is placed on a heated operating-table and the operation fields are prepared by clipping, shaving, and washing the skin The E C G and E E G electrodes and the œsophageal thermometer lead are inserted, and the diathermy earth electrode is applied Benethamine penicillin 600,000 units and streptomycin 0 5 g are given intramuscularly An intravenous drip through a Guest cannula is set up in the cephalic vein The clotting-time of the venous blood is done by the Dale and Laidlaw (1911) method 1 mm nylon cannulæ for the manometers are inserted into the abdominal aorta and inferior vena cava through the femoral vessels

A longitudinal incision is made in the neck for access to the left common carotid artery A right fourth interspace thoracotomy is made to expose the heart and the great vessels (In the last eight perfusions a bilateral transternal thoracotomy has been carried out, allowing left brachial instead of carotid cannulation) Before the vessels are cannulated heparin 2 mg per kg is given intravenously Thin rubber tubes are passed around the superior and inferior venæ cavæ at their junction with the right atrium to act as tourniquets The arterial cannula is of the design described by Drew et al (1957), but the rigid parts are of nylon In only two dogs have we failed to insert an arterial cannula at least 3 8 mm in internal diameter The venous cannulæ, which are simple vinyl tubes, have never been of a smaller internal diameter than 4 mm and are usually 6 mm (For the first thirty experiments they were passed into the venæ cavæ through separate auricular incisions, but now a single incision is made in the auricular appendage and the

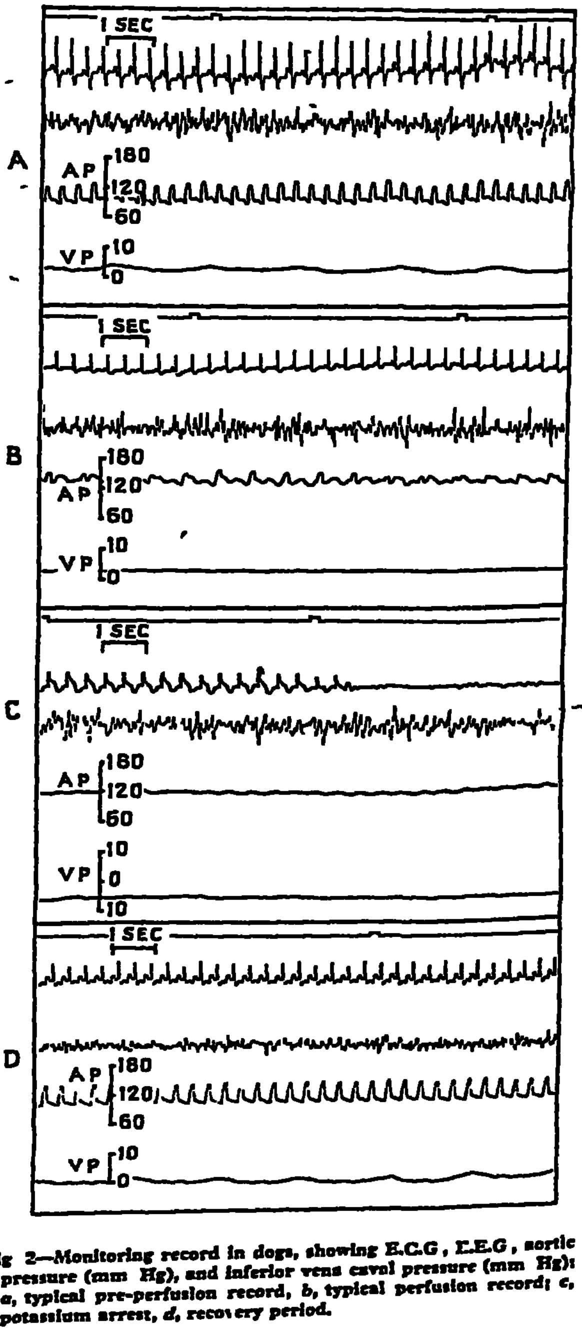

Fig 2—Monitoring record in dogs, showing E.C.G , E.E.G , aortic pressure (mm Hg), and inferior vena caval pressure (mm Hg): *a*, typical pre-perfusion record, *b*, typical perfusion record; *c*, potassium arrest, *d*, recovery period.

cannulæ are passed through two holes bored in a sponge-rubber grummet inserted in this incision.)

During the whole of the operation meticulous hæmostasis is maintained, the total blood-loss, including that due to cannulation, is rarely as much as 30 ml. before perfusion, measured by swab-weighing.

The Perfusion

Immediately before connecting the hoses to the cannulæ the blood is circulated for a minute and the hoses are again inspected for the presence of bubbles on the arterial side. A bubble-free junction is then made between the arterial hose and the arterial cannula. The venous hose is joined to the two venous cannulæ by means of a stainless-steel Y tube, small bubbles being of no moment. Perfusion is begun by starting the machine, unclamping the hoses, and tightening the caval tourniquets. The animal is then on total cardiac bypass. We have never failed to achieve satisfactory perfusion as evidenced by adequate arterial-perfusion pressure (80/60 to 140/100 mm. Hg), and a satisfactory grade of E.E.G. (Hudson 1958) (fig. 2). The main task of the pump operator during perfusion is to maintain a constant volume in the helix. If perfusion is unsatisfactory, it is corrected on information from the monitor and from the pump operator.

On sixteen occasions simple perfusion varying in duration from 10 to 75 minutes has been performed. In the remaining experiments, satisfactory perfusion having been established, a further procedure has been carried out. In six perfusions the heart has been arrested with potassium citrate and in the remaining twenty a right ventriculotomy has been performed, sixteen of these on the potassium-arrested heart (see accompanying table and fig. 3).

Potassium Arrest

The first five potassium arrests (Melrose et al. 1955) were done by aortic injection, but this resulted in such troublesome bleeding from the puncture that all subsequent arrests were done by injection into the left ventricle. None of the twenty-two hearts arrested with potassium has failed to restart and ultimately to maintain effective circulation with a normal arterial pressure. The period of recovery, however, has been as long as 25 minutes, and has been punctuated by episodes of atrioventricular dissociation, ventricular asystole, ventricular tachycardia, and ventricular fibrillation. Ventricular asystole and bradycardia due to heart-block occurring after the heart is closed cause distension of the heart due to coronary-sinus return, and on these occasions an artificial pacemaker (Lightwood 1958a) has been used to stimulate the heart to eject its contents. Ventricular fibrillation has been stopped by an electrical defibrillator, employing a 300-volt D.C. shock of 1/50 second duration (Lightwood 1958b). Cardiac bypass has always been maintained until sinus rhythm has been re-established and effective left ventricular ejection observed on the aortic pressure tracing.

Perfusion is ended by releasing the caval tourniquets, stopping the pump, and simultaneously clamping the arterial and venous hoses. The arterial and venous cannulæ are removed, the artery and the right auricular appendage are ligated and transfixed.

Closure

Protamine sulphate 0.5% is given very slowly intravenously until a total of 2 mg. protamine for each mg. heparin used has been given. The clotting-time is then repeated and increments of protamine 0.25 mg. per mg. heparin are given if necessary until the clotting-time is within 20 seconds of its original value. We think this is preferable to protamine titration (Perkins et al. 1956), which is slow and complicated. We have had no difficulty in restoring the clotting-time to normal and

P = simple perfusion. K = perfusion and elective potassium arrest. V = perfusion and right ventriculotomy.
'Walking-time' = time from insertion of last stitch to walking. Kd = killed on or after 14th postoperative day (excluding dog 42, killed at 9 days).

saturated fatty acids in high concentration may be consumed without raising cholesterol levels above the "basal value" for the individual * Our experience indicates that the basal values are about 30% below the levels ordinarily found in Western society Perhaps modification of foodstuffs may enable us to achieve the blood-cholesterol levels now seen in populations which have low morbidity and mortality from atherosclerosis

We are indebted to Dr A T James, of the National Institute for Medical Research, Mill Hill, for the analytical data One of us (L H) receives a grant from the National Research Council, Canada

SERUM-CHOLESTEROL LEVELS AFTER CONSUMING EGGS WITH INCREASED CONTENT OF UNSATURATED LIPIDS

The rise in serum-cholesterol level which follows consumption of hens' eggs is something of an enigma It is not due to their cholesterol or protein content,[1] [2] and it is generally attributed to a fatty-acid factor Egg-yolk lipids, however, are only moderately saturated (iodine value 70–80)[3], and their cholesterogenic effect is greater than would be expected on the "degree of saturation" hypothesis of Ahrens et al[4] Furthermore, egg-yolk lipids contain about 20% of linoleic acid[5] (in addition to 32% of saturated fatty acids, 47% of oleic acid, and 2% of linolenic acid) and thus their cholesterogenic effect cannot readily be explained in terms of the essential-fatty-acid deficiency postulated by Sinclair[6] and by Kinsell et al[7]

While considering this we recalled an old report by Cruickshank,[5] who found that when hens were fed on a diet rich in hempseed, the linoleic-acid content of their yolk lipids rapidly rose from 19 to 44%, with a corresponding fall in saturated and oleic acids, at the same time, the iodine value of the yolk lipids rose from 80 to 120 Accordingly, in the hope of shedding some light on their cholesterogenic mechanism, we decided to compare the effects of ordinary and "unsaturated" hens' eggs on the human serum-cholesterol level

A flock of Black Australorp hens was chosen for our experiments During an initial 2-week control period they had a stock diet containing 3% of fat with an iodine value of 93 Eggs were collected on four occasions, and the iodine value of their yolk lipids averaged 72 (S D 1) Half the hens were then placed in a separate henhouse and were given a special feed which included sunflower seeds (80% dehulled) The other half continued with their ordinary diet The composition of the control and the experimental feeds is shown in the table

Percentage composition of the hen feeds

	Control feed	*Experimental feed*
Mealie meal	59·0	31·0
Bran	11 0	4 3
Lucerne meal	11 0	8 7
Peanut-oil cake	5 0	
Fish meal	6 5	3·5
Limestone powder	2 0	3 5
'Fermavite' (molasses fermentation product)	1·0	2 5
'Premix' (commercial bone-meal and salt mixture)	4 5	3 5
Sunflower seeds (80% dehulled)		43 0
Percentage fat contents (by analysis)	3·0	15 0

From now on four eggs were gathered from each hen house weekly The yolk lipids from the hens on the experimental feed showed a progressive increase in iodine value, and by the end of 3 weeks this had reached 100, at which level it remained for the duration of the experiment The iodine value of the yolk lipids from the control hens did not change and at 3 weeks averaged 73 (standard deviation 1 5) At this stage all the eggs from the control and the experimental hens were collected and used for human feeding trials The experimental egg yolks were a deeper yellow than the controls, but when they were cooked they could not be distinguished by taste

The experimental hens throve on their diet, and their egg-production was in no way inferior to that of the controls It interested us to find that, after the 6 weeks, the mean serum-cholesterol level of the ten experimental hens was 117 mg per 100 ml (S D 23), compared with 166 mg (S D 34) these mean values were significantly different (P less than 0 02) By this time the body fats of the experimental hens had become relatively unsaturated the values for the control and experimental hens respectively were abdominal fat, 76 and 94, subcutaneous fat, 76 and 85, muscle fat, 77 and 91, liver fat, 77 and 90 Too few analyses were performed, however, to permit of any statistical comparison

The effect of feeding these eggs was studied in 2 healthy Bantu male volunteers, each 34 years old During the experiments they lived in the metabolism ward and received the basal diet, very low in fat (11 g daily), which we have previously described[2] Except as indicated below, their diets were kept constant with respect to calories (2500 daily) and protein (88 g daily)

Experiment 1 (fig 1)—On the basal diet, the mean serum-cholesterol level was 75 mg per 100 ml Introduction of ten boiled "control" egg-whites into the daily diet for 10 days did not alter it When they were replaced by ten boiled control egg yolks daily for 10 days, it rose to 100 mg These were then replaced by ten boiled "unsaturated" yolks, and during the next 10 days the serum-cholesterol level fell to 95 mg per 100 ml —a trivial change In the next period, ten whole "unsaturated" eggs fried in 100 g of sunflower-seed

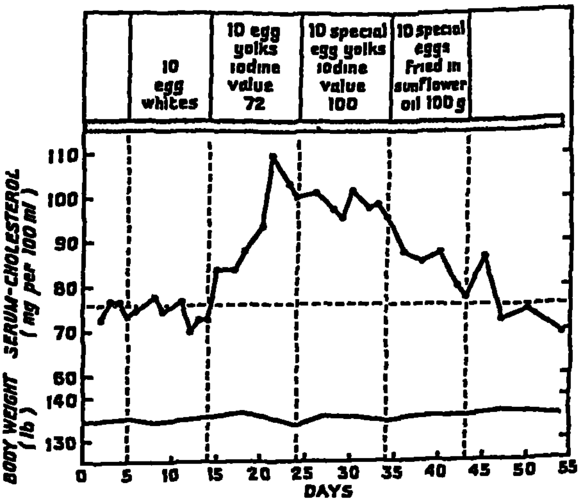

Fig 1

---

* Since this communication was first submitted, two more subjects have been tested The ingestion of ten eggs daily (high in unsaturated fatty acids) resulted in a gradual return of the serum-cholesterol levels from low-fat basal levels to control levels in a 2-week test period With stock eggs, the serum-cholesterol rose more abruptly and reached higher levels

oil were eaten daily (3100 calories, 112 g. protein), and by the 9th day the serum-cholesterol level fell to 77 mg.—i.e., practically to basal level. On returning the subject to his basal diet there was a temporary rise in the serum-cholesterol, but it quickly returned to the basal level.

In this first experiment there was no difference in the effect on the serum-cholesterol level of "control" and "unsaturated" eggs. It remained possible, however, that if the latter had been eaten for more than 10 days the cholesterogenic effect of the control eggs might have been reversed. In the next experiment, therefore, the unsaturated eggs were fed without a preliminary period on control eggs.

Experiment 2 (fig. 2).—During an initial 6-day basal period, the serum-cholesterol level averaged 188 mg. per 100 ml. Then ten boiled unsaturated egg yolks daily were introduced into the diet and fed for 7 days; the serum-cholesterol level promptly rose to 218 mg. The subject was then returned to his basal diet and 3 g. of cholesterol daily (i.e., the amount in ten yolks) was mixed with his food for the remaining 8 days of the experiment. The serum-cholesterol quickly returned to the basal level, and this showed again that the serum-cholesterol-increasing action of eggs is not due to their cholesterol content.

It appears from these two experiments that increase of the iodine value of egg yolks from 72 to 100 does not materially affect their cholesterogenic action. Although egg-yolk lipids with iodine value of 100 markedly raise the serum-cholesterol level, we have frequently observed that certain other more saturated fats, such as hydrogenated sunflower seed oil (iodine value 74), do not raise the serum-cholesterol, and that some, such as olive oil (iodine value 88) and peanut oil (iodine value 89), sometimes lower it. Thus we conclude that the effect of all dietary fats on the serum-cholesterol level is not simply a function of their degree of saturation.

The suggestion of Keys et al.[8]—that, to offset the cholesterogenic effect of saturated fatty acids, at least twice as much polyethenoid fatty acid is required—might appear to be a satisfactory explanation of our findings; thus, the additional linoleic acid introduced into the unsaturated eggs may not have sufficed to neutralise their saturated-fatty-acid content. In Cruickshank's experiments,[3] the polyethenoid-fatty-acid content of her unsaturated eggs was more than double their saturated-fatty-acid content; had we been able to "unsaturate" our eggs beyond iodine value 100, it is conceivable that we might have produced a "cholesterol-decreasing" egg. It must be noted, however, that in several other dietary experiments in man, a fall in serum-cholesterol has been produced with far less than a 2 : 1 ratio of polyethenoid to saturated fatty acids. For example, fig. 8 of our paper last December,[9] shows that the cholesterogenic effect of 100 g. of hydrogenated coconut oil (almost all saturated fatty acids) was abolished by 100 g. of sunflower-seed oil—i.e., by only 65 g. of linoleic acid. In a number of long-term studies of active men consuming their ordinary diets, which were often rich in saturated fats, we found that by simply administering 50 g. of sunflower-seed oil (about 33 g. of linoleic acid) daily, a substantial decrease in the serum-cholesterol level was usually produced and maintained.[10] It may be that the rule of Keys et al.[8] is valid when applied to their type of "group" experiment but we agree with Kinsell[11] that the *individual* response to a dietary fat is variable and cannot be predicted by a mathematical formula.

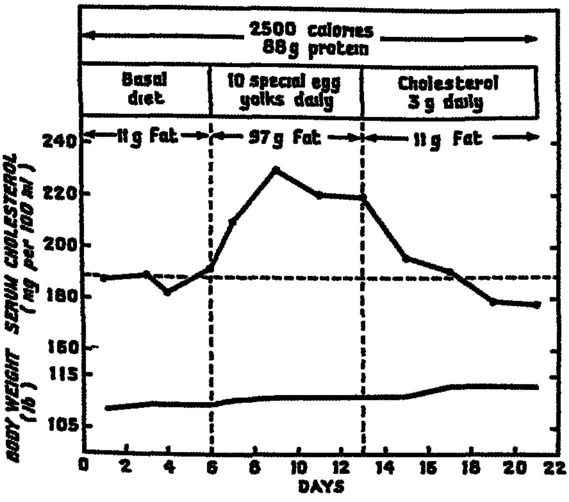

Fig 2

We have no data on the individual fatty-acid components of our control and unsaturated egg yolks, but on the basis of Cruickshank's findings[3] we have assumed that the unsaturation of the latter is achieved by an increase in the proportion of linoleic acid at the expense of the monoethenoid and saturated fatty acids. Failure of this presumed rise in the linoleic-acid content of our eggs to inhibit the cholesterogenic effect seems to be at variance with the "essential fatty acid deficiency" hypothesis. We must point out, however, that it is not known whether the "linoleic acid" of egg yolks is the biologically active *cis-cis* isomer or not. It is known that the "linoleic acid" of a number of animal fats is in the inactive form,[12] isomerisation apparently having taken place in the process of digestion, absorption, or deposition of the active linoleic acid of the diet. Thus, Hilditch and Longenecker[13] found that, despite an abundance of natural linoleic acid in pasture grasses, the depot fats of ruminants contain very little of it; most of the octadecadienoic acids of these fats are in the *trans-cis* or other isomeric forms. It is possible that the failure of our unsaturated egg yolks to decrease the serum-cholesterol level is due to isomerisation of the linoleic acid of the dietary sunflower seeds in the course of its incorporation into the egg yolk.

The above speculation implies acceptance of the "essential fatty acid deficiency" hypothesis. This hypothesis, however, is far from proven: hypercholesterolæmia does not occur in animals fed on a diet deficient in essential fatty acids,[14] nor is there any direct evidence of such deficiency in hypercholesterolæmic human beings. It is true that Kinsell et al.[7] have shown that 95% pure linoleic acid can lower the serum-cholesterol level of man, but the effect of its "non-essential" isomers has not been studied. We must conclude that the factor or factors in dietary fats which regulate the serum-cholesterol level are still unknown.

These experiments were performed with the cooperation of Dr M. Finlayson, the owner, and Mr J. Mirvish, the manager, of the farm Kelvin Grove in the Constantia valley. We are grateful to them for their kindness.

Reviews of Books

Clinical Biochemical Methods

A L TÁRNOKY, B SC, PH D, biochemist, Royal Berkshire Hospital, Reading London Hilger & Watts 1958 Pp 239 50s

MOST departments of clinical biochemistry or chemical pathology have a "methods book", which contains, usually in alphabetical order, descriptions of the techniques used in the department These are concise résumés but leave out no essential detail The junior technicians use this collection of recipes rather as a young housewife would her cookery book, and the more senior members of the laboratory refer to it for a quick refresher To be entered in such a laboratory book is high praise for a technique because it implies that it has been tested by the worker on the bench, found reliable and worthy of becoming a part of his everyday routine There is a tendency to adhere to one particular method once it has been accepted and not to bother about minor or sometimes even major improvements the accent is on reliability and convenience rather than on striving to be entirely up to date Dr Tárnoky's book is such a one, describing "the biochemical analyses in routine use in the laboratory of the Royal Berkshire Hospital"

Most methods required in clinical biochemistry are here assembled, but the natural history of such a summary of techniques explains why the choice is somewhat uneven Thus the method for estimating serum-calcium is the old-fashioned precipitation of the calcium as oxalate and the subsequent titration of the oxalate by permanganate On the other hand, serum-chloride is determined by the swift titration with mercuric nitrate with diphenylcarbazone as the indicator Serum electrophoresis for separating protein fractions is described, but no mention is made of the determination of urinary amino-acids and sugars by chromatography, or of the instantaneous identification of glucose in urine by the use of test papers or sticks containing glucose oxidase The urine tests are somewhat neglected Sulkowitch's test for calcium and Bial's test for pentoses (though the osazone test is mentioned) might have been included No test for fructose in urine is given It might be questioned whether anyone can describe satisfactorily the determination of the basal metabolic rate, of alkali reserve, of serum-protein fractions by electrophoresis within a few pages each Yet as far as he can go Dr Tárnoky has produced here masterpieces of concise clarity This book will be particularly useful in hospital laboratories which do not include a biochemical department and where a morbid anatomist must take responsibility for the reliable biochemical investigation of hospital patients

A History of Public Health

GEORGE ROSEN, M D, PH D, M P H, professor of health education, School of Public Health and Administrative Medicine, Columbia University New York M D Publications 1958 Pp 551 $5 75

THE history of public health is the story of man's endeavours to protect himself and his community against disease and of the attitudes of society towards the sick throughout history In primitive communities, down to the Middle Ages, society's defence against sickness, physical or mental, was to isolate or destroy the patient, later came the endeavour to heal the sick and so prevent them from infecting or harming their fellow men or becoming a burden on society, and finally the establishment of positive protection of the healthy from the dangers of disease

Professor Rosen has long been recognised as one of the world's foremost medical historians and an acknowledged leader in matters of public health Here, in the first of a new series of monographs on medical history, his pen has skilfully traced the procession of men, deeds, and facts that have taken a vital part in the story of public health, and the tremendous tasks that had to be faced

As late as 1808 the inhabitants of Exeter emptied their sewage in the gutters, and in the entire town there was only one water-closet The introduction of this amenity, however, soon created more problems than it solved, since the cesspits were cleaned out very rarely and the contents seeped into the soil, saturating the ground over large areas and polluting springs and wells It was deceptively easy to dispose of sewage by allowing it to discharge into the sewers that existed under many cities by this time, but they were solely designed to carry off rainwater, and so, as the practice became more general rivers and lakes in or near all the larger towns were turned into open sewers This was to be one of the major problems facing the sanitary reformers of the nineteenth century

The book is well documented and contains an appendix of short biographies

Heart Disease and Pregnancy

Physiology and Management C SIDNEY BURWELL, M D, Samuel A Levine professor of medicine, Harvard University, JAMES METCALFE, M D, associate in medicine, Harvard University Boston Little, Brown & Co London J & A Churchill 1958 Pp 338 72s

THIS work is based on the authors' experiences in the Boston Lying-In Hospital It begins with a brief historical survey showing the dramatic fall in maternal mortality from heart-disease in the hospital between 1921 and 1927, and a further decline in 1937–39 There follows a full account, well illustrated by graphs, of the physiological maternal changes in pregnancy Other chapters deal with the incidence of heart-disease among pregnant women, diagnostic criteria for heart-disease, prognosis, maternal and fœtal mortality, and the management of the pregnant patient with heart-disease, with special reference to the indications for termination of pregnancy A chapter is devoted to rheumatic fever in pregnancy, and the remainder of the book covers the problems of pregnancy in different forms of congenital and acquired heart-disease Particular attention has been paid to mitral stenosis and the question of valvotomy in pregnancy The concluding chapters cover less common types of heart-disease and neurocirculatory asthenia This book will undoubtedly prove of great value to physicians, obstetricians, and cardiologists, its great merit being the emphasis on the extensive personal experience of the authors

Hypnography

AINSLIE MEARES, M B, D P M Springfield, Ill Charles C Thomas Oxford Blackwell Scientific Publications 1957 Pp 271 58s 6d

DR MEARES has for some years done pioneer work in the field of hypno-analysis, and this clinical study, well written and thoughtfully presented, will interest any psychotherapist aware of the value of hypnosis A description of the preliminaries to hypnosis, the methods of inducing hypnosis, and the technique for hypnography itself leads to an account of the kind of material produced The patient, hypnotised while sitting at a desk, is given a brush and black paint and it is suggested that he shall paint whatever is in his mind The drawings thus produced are illustrated in a series of over 200 figures, and their dynamic content discussed, both in general terms and specifically in excerpts from case-histories The book might have been less expensive if some of the figures had not been duplicated

---

A Short History of the Order of St John (London St John Ambulance Brigade Headquarters 1958 Pp 83 2s 6d)—The black and white uniforms of the St John Ambulance Brigade are a familiar sight at all our public functions But few realise that the men and women who wear them are lineal descendants of the knights of one of the oldest known orders of chivalry And many members of the Brigade would themselves find it hard to say how long ago the Order was founded, or how its present functions have evolved This booklet by Mr E D Renwick sets out in easy and attractive style a story which begins in the twelfth century in Amalfi, a small republic south of Naples, and which continues to the present day, for the eight-pointed white cross, once the badge of that republic, is still the emblem of the Order of St John The account is freely illustrated All those doctors who have been associated with the Brigade would do well to read it, they may well feel, after its perusal, that their stature has increased
